It might well be suggested that, if there exist such an interest in medical matters among the newspaper reading public, it would be to the advantage of journalism to have a doctor on the permanent staff as general adviser and writer on all that concerns medicine. This suggestion may have been put into practice, though personally I cannot recall any instance of its adoption. There are objections to it which are fairly obvious. In the first place it is possible that a qualified doctor who accepted such a position on the staff of a newspaper might be running foul of some of the conventions of the General Medical Council. Even if it was otherwise, I am somewhat doubtful whether such an experiment would succeed. One of two things would happen: either the medical correspondent would absorb the spirit of his environment and become more of a journalist than a sober *terre-à-terre* doctor, or he would retain the restraint, reticence, and admirable dignity of his profession and be useless as a member of the staff of a newspaper. Besides all this, I doubt very much, except in cases of young doctors still in search of a practice, whether the career of journalism would be tempting enough for a man who has spent four to six years to qualify. It would be a bad thing for both medicine and journalism if incompetent men were engaged.

Owing to the restrictions to which I have referred we journalists are limited in our endeavours to act as interpreters for your profession to the people. We are driven, therefore, to the published words of eminent physicians or surgeons over whom the General Medical Council does not seem to exercise control. Here we are met with the difficulties of such a divergence of opinion as to render our efforts nugatory. Take diet for example. Sir A.B., a physician with a most distinguished record, says alcohol is poison. Sir B.C. makes a speech and pronounces it to be a most excellent and salutary stimulant when taken in moderation, and confesses that he himself always takes a nightcap. "Beer," says Sir D.E., "is both drink and food. Taken in moderation it is an excellent digestive, a magnificent and safe pick-me-up, and should be on every table in the land." Whereupon Sir F.G. declares that if a man has any sort of regard for his liver, he should not even smell an empty beer-pot, much less drink the vile stuff. If people will drink, let

them drink light wines, whisky, or egg-flip. Who will decide when doctors disagree?

So far, I am afraid that you will think that I have been a little lukewarm in my advocacy of joint action between the doctors and journalists. This, however, is not the case. If I have mentioned particular circumstances under which co-operation between the two has been somewhat difficult, I have no hesitation whatever in declaring that on the broad question of the presentation of the plain facts of health there can be, and there should be, the most hearty and constant collaboration of the two professions.

There will be moments in our national life when disaster can only be averted by the combination of medicine and journalism. Epidemics may rage again, and the people will require daily warnings and advice. When this happens I feel sure that the doctors can call on the press to help, and that call will receive an immediate and enthusiastic response. The seasonal ills of spring, summer, autumn, and winter are topics of interest to the press, and we gladly receive and print the advice so generously placed at our disposal by your great profession. Every day there is made some advance in the great science of medicine, and if, as is right and proper, you are reluctant to raise hopes too soon, or to divulge a secret until it has been thoroughly tried out, we, too, are willing to keep silent until the right time for discovery has come. To enforce the simple rules of health which are approved by your profession, to save the people from expensive and dangerous quacks, to do all that is in our power to make of our people the healthiest, as they are the sanest, in the world—these are noble aims worthy of the great professions to which you and I belong.

The Sections.

SUMMARY OF PROCEEDINGS.

SECTION OF MEDICINE.

Thursday, July 25th.

TREATMENT OF PLEURITIC EFFUSION.

DR. H. J. STARLING (Norwich) presided over the second session of this Section, when SIR THOMAS HORDER read a paper on the treatment of pleuritic effusion. First enumerating the various factors of importance that had to be considered in any case, the speaker went on to uphold the traditional division of effusions into serous and purulent, and enumerated their various causes. He emphasized the fact that it was bad practice to remove all effusions at sight, whether they were serous or purulent; before the fluid was tapped the associated condition of the lung must be assessed as carefully as possible, and it must be determined how far the patient was embarrassed by the fluid itself. In a general way the more ill the patient the more carefully and slowly should the fluid be removed. Speaking more particularly of serous effusions, Sir Thomas Horder argued that too early intervention was meddlesome; if postponed till unduly late it might result in permanent collapse of the lung. Strapping of the chest was often advantageous, and so might be the exhibition of iodides and even calcium. Little good could be said of autoserotherapy. Once tapping had been determined on, slow aspiration was preferable to siphonage, and a portion only of the effusion should be removed. Local anaesthesia and the preliminary use of a sharp scalpel were to be recommended. It must be remembered that most serous effusions were tuberculous in origin, and a prolonged convalescence was indicated. Turning to empyema, the speaker advocated the removal of the pus as soon as it was diagnosed. One or two aspirations might be successful in pneumococcal and in some septicaemic cases (streptococcal). should the patient be too ill to stand the resection of a rib, or open method, that was most generally advisable. But rarely could the septic cavity be opened, emptied cleaned out, and closed up again with success. It was important to disturb the diseased lung as little as possible; irrigation of the diseased cavity, though it had been tried again and again, was of but doubtful virtue, whatever the nature of the irrigating fluid. DR. L. S. T. BURRELL confined his remarks to exudates of doubtful or tuberculous origin. The great majority of pleural exudates were due to tuberculosis, so that, unless there was any definite evidence to the contrary, it was safest to base treatment on the assumption of a tuberculous origin. The patient sought advice in most cases either because of acute pain from pleurisy—the effusion develops later—or because of dyspnoea and general malaise; he was found to have a pleural effusion. In the latter case it might be possible to obtain a history of previous pain for which the patient did not see a doctor, but in many cases there was no history of any pain or illness, and the sole complaint was increasing dyspnoea. In either case the patient should be put to bed and 5 c.cm. of the liquid should be aspirated for examination, because treatment was largely dependent upon the character of the effusion, and a cytological examination helped to determine the cause. Aspiration should not be performed except (1) to relieve pressure symptoms such as dyspnoea; (2) to convert the condition into one of artificial pneumothorax if the underlying lung was actively tuberculous; (3) to encourage the underlying lung to re-expand owing to active disease in the other lung; (4) to treat chronic or recurrent pleural effusion. Removal of a quantity of liquid from the chest was not free from danger, and had led even to sudden death. More common complications, however, were violent paroxysms of cough, severe dyspnoea, oedema of lung, or activation of a tuberculous lesion which was previously quiescent in the lung. In order to prevent these dangers it was wise to introduce air or oxygen into the pleural cavity if more than 15 ounces of liquid were withdrawn. Air should be used if it was desired to maintain an artificial pneumothorax, and oxygen if one wished the lung to re-expand, because oxygen was more rapidly absorbed than air. In an acute case with high fever and toxaemia the effusion was the result and not the cause of the condition, so that although it was often necessary to aspirate in order to relieve pressure symptoms resulting from a rapidly accumulating effusion, in the absence of such pressure symptoms it was very rare that aspiration would relieve the toxaemic symptoms; indeed, it would often make them worse. Most of the acute cases settled down and did best without aspiration. In the very chronic or recurrent cases aspiration should be performed and the pleural cavity gently irrigated with Dakin's solution; oxygen introduced, and a negative pressure of about 6 in. of water left. The general condition of the patient should be treated by fresh air, good food, and, if necessary, aperients, tonics, etc., but no drug had any effect on the actual effusion. The after-treatment was of the greatest importance, for on it might depend whether the patient became consumptive; 40 per cent. of such cases subsequently developed pulmonary tuberculosis, and sanatorium treatment was the best for them. PROFESSOR A. RAMSBOTTOM (Manchester) said that all the evidence went to show that idiopathic pleurisy was in the vast majority of cases tuberculous; cold and injury, important medico-legally, were merely predisposing. It was noticeable how few soldiers, after chest wounds in the war, contracted pulmonary tuberculosis. Although by ordinary methods the bacilli could seldom be demonstrated in the fluid, by modified methods the bacilli had been found in seventeen consecutive cases. These observations were also borne out by inoculation experiments, and by following up the cases (43 per cent. within six years). Tuberculous pleurisy was rarely if ever primary; it was secondary to tuberculosis elsewhere, usually the lungs. The presence of pleural effusion was usually readily determined by clinical examination. It was frequently noticed that the affected side was smaller than the sound side, due no doubt to the fact that when effusion began the cohesive property of the pleural surfaces was lost; the lung collapsed and overprepared for effusion, with the result that the chest wall fell in. Bulging of intercostal spaces, or increase in size of the affected side, usually indicated positive intrathoracic pressure. This collapsing of the lung on the affected side played a most important part in the displacement of the heart in the early stages, and in cases

of moderate effusion by allowing it to be dragged over by the traction of the sound lung. Therefore displacement of the heart was one of the most important, if not the most important, of the physical signs of pleural effusion. Considerable time should therefore be spent in locating the position of the heart; one fallacy had to be borne in mind —the base of the lung on the affected side often retracted, exposing the heart up to its margin. Withdrawal of the fluid should not be hurried, but, if the fluid was left too long, permanent impairment of breathing might result. Provided that the fluid was serous, removal was undertaken under two conditions: (1) At any time should the signs of positive intrathoracic pressure supervene. (2) If with the subsidence of the temperature there was no evidence that absorption was taking place. It was very unsatisfactory to remove fluid before the temperature had subsided, for as a rule it rapidly accumulated again. In distinguishing serous from purulent effusion, tenderness of the chest wall was a useful positive sign.

Dr. RUSSELL dissented from Dr. Burrell's view that most cases of serous pleuritis should be treated as if they were tuberculous. His own experience in these cases was very different. Professor G. R. MURRAY (Manchester) advised the immediate removal of a serous effusion if it reached as high as the fourth costal cartilage. He recommended light freezing with ethyl chloride spray as the local anaesthetic for the paracentesis, and spoke highly of convalescence at high altitudes for such patients. He had had no experience of the treatment of empyema by aspiration alone. Dr. M. ASTON KEY (Southsea) referred to many of the difficulties met with in the diagnosis of empyema; in the case of children he had found it unnecessary to resect a portion of a rib in draining the abscess. Dr. J. SPEARES (Dublin) discussed a number of the difficulties met with in treating empyemas, particularly in cases in which healing of the operation wound is long delayed. He recommended breathing exercises in the after-treatment, and stated his preference for Dieulafoy's aspirating apparatus. Dr. ASTLEY CLARKE (Leicester) advocated siphonage rather than aspiration in the removal of pleuritic effusions; and recorded his conviction that most simple serous effusions were tuberculous in origin. Children, after an empyema operation, might with advantage be allowed to irrigate the cavity by being put to sit in a bath of warm boric solution. He had met with a single case of death due to pleural shock.

Dr. WILLARD J. STONE (Pasadena, California) said that in the experience of the United States Army empyema operations performed early without preliminary repeated aspirations were followed, in about fifty cases, by a high mortality (approximately 64 per cent.), which resulted from an open pneumothorax with collapse of both lungs before the mediastinum had become mobilized by adhesions; since it had been shown that, before mobilization had occurred, for practical purposes the two sides of the pleural cavities existed as one. The mortality was also influenced by operations for drainage before the areas of consolidation had cleared up in the lung on the opposite side. When the plan was followed of treating such cases by repeated aspirations, with rib resection after twelve to fifteen days, the mortality was reduced in a series of 100 cases to 16 per cent.; in the next series of 100 cases the mortality in cases so treated was 9 per cent., while in the last series of 100 cases the mortality was 8 per cent. The haemolytic streptococcus was largely responsible for the empyemas in the series, regardless of the type of pneumonia which preceded; this was, however, to be expected, especially in the pneumonia of measles. A large percentage of the soldiers in the camp where the pneumonias occurred were throat carriers of haemolytic streptococci. The complications producing death after empyema operations were: (1) purulent pericarditis; (2) septic peritonitis; (3) substernal mediastinal pus pockets often associated with purulent pericarditis by contiguity; (4) so-called septic nephritis; (5) meningitis. The figures given previously referred largely to the pneumonia following measles (bilateral streptococcal pneumonias), and to lobar pneumonia in which the complications were largely due to *Streptococcus haemolyticus* in throat carriers of the infection. In epidemic influenza pneumonias fewer empyemas were encountered among 15,000 cases treated at the same hospital later in 1918 (Camp Funston), since the infection, whatever its nature might ultimately be proved to be, produced death in about 25 per cent. within two or three days, before there had been time for an empyema to develop. In the relatively few empyemas which followed among those who survived their pneumonia, the haemolytic streptococcus was again found as the predominating causative organism. The work of the Empyema Commission later appointed by the Surgeon-General confirmed the clinical observations which had led them to adopt conservative measures in the treatment of empyema early in 1918, and to the so-called early aspiration-late operation plan. Instillations of large quantities of anti-streptococcal serum into the pleural cavities of empyema patients were not followed by improved results. Cases of empyema developing sporadically in pneumonia not existing in epidemic form might be expected to have a more favourable outcome than in a similar series of cases occurring during the course of an epidemic in which increased virulence might play an important but little understood part. The CHAIRMAN recorded his own experience with the continuous drainage and aspiration of empyemas, which was not too satisfactory; the method seemed only to postpone the usual operation of rib resection. Replying to a number of questions, Sir THOMAS HORDER recommended novocain and adrenaline for local anaesthesia; he had seen three sudden deaths apparently due to pleural shock, one occurring on pleural puncture, the other two following irrigation of an empyema cavity. Exercises for expanding the lung should not be begun too soon after the tapping of the chest; and vaccine treatment gave disappointing results in empyema. Dr. BURRELL, also answering questions, said that he had met with three instances of sudden death from paracentesis thoracis. The meeting of the Section was well attended, over ninety members being present at one time.

SECTIONS OF SURGERY, AND PHYSIOLOGY AND BIOCHEMISTRY.

Thursday, July 25th.

ABDOMINAL PAIN.

AT this joint meeting, on July 25th, with the President of the Surgical Section, Professor E. D. TELFORD, in the chair, Dr. CHARLES H. MAYO (Rochester, U.S.A.) opened a discussion on abdominal pain by remarking that abdominal pain when not due to peritoneal involvement was dependent either on violent contraction or extreme distension of a viscus. Poulton and Payne had shown recently that pain might be felt during the relaxation of a peristaltic wave. Anaemia of the bowel wall from contraction, or possibly lack of oxygen, might be the cause of visceral pain. Solid viscera were also sensitive—for example, the liver and ovary. The anatomical side of the problem was adequately dealt with, and the presence of true sensory fibres in the splanchnic nerves was emphasized. The speaker described the viscero-sensory reflexes associated with diseases of the gall-bladder and stomach, and said that realization of the inadequacy of knowledge of abdominal pain was made manifest in the surgical treatment of the gastric crises of tabes. The types of gastric crisis were described, and it was stated that complete denervation of the entire stomach had failed to abolish the pain, but some relief had been obtained from cutting the spinothalamic tracts. The study of the surgery of tabetic crises showed clearly how diverse were the sensory paths from the stomach. Severe localized and long-continued pain in a localized abdominal area might possibly be due to bacterial involvement of the requisite spinal nerve. The pain of peptic ulceration might be compared with the pain of varicose ulceration; it was perhaps due to vascular spasms, and later to small extensions at the margins. Summation of stimuli acting on an abdominal viscus might produce pain, while such stimuli acting singly would not be felt. Sound knowledge of abdominal sensations facilitated earlier diagnosis. Sir FARQUHAR BUZZARD (Oxford) said that the problems of the sympathetic nervous system were fundamentally different from the rest of the nervous system. Normally the visceral nervous mechanism did not affect the higher cerebral

centres, but when irritating material was present in the lumen of a viscus there were spasmodic contractions of the involuntary musculature of the organ reinforced by the skeletal musculature, and giving rise to the clinical picture of colic. Splanchnic pain was certainly real, and since the organs were insensitive to ordinary painful stimuli the absence of pain receptors was assumed, the pain being due to stimulation of nerve fibres. The speaker referred to the variations in the threshold of pain sensibility, and also to the persistence of a low pain threshold after all structural abnormality had been removed or disappeared. Knowledge of the length of time during which this low threshold existed would throw much light on certain chronic abdominal conditions. The hypersensibility of some patients might be more fairly attributed to a derangement at the sympathetic rather than the higher levels of the nervous system. Certain heteronomous types of abdominal pain were referred to: coronary thrombosis, "angina abdominalis," and the gastric crises of tabes. In the latter condition examination of the knee-jerks only gave information of a tabetic lesion at the lumbar level of the cord, and therefore was of little use. The type of pains, the intense superficial hyperaesthesia with comparatively slight rigidity, were characteristic features. Mr. John Morley (Manchester) said that his observations of the pain in appendicitis were incompatible with Mackenzie's theory of the viscero-sensory and viscero-motor reflexes. The appendix was developmentally a median organ; it would therefore have a bilateral splanchnic nerve supply, and to accord with Mackenzie's theory the pain and tenderness should be bilaterally symmetrical. After the passing of the initial pain, and before perforation occurred, the remaining pain, tenderness, and rigidity were unilaterally situated. Again, the localized deep tenderness and rigidity in an early case of appendicitis was an undoubted fact, and the precise position of the organ could be determined. The same phenomenon was present in early acute obstructive cholecystitis, and, as the gall-bladder enlarged, the area of maximum tenderness and rigidity spread downwards. The splanchnic nerve stimulation did not cause the rigidity, otherwise the pain would remain in the same situation. The change of position was proof of its origin from the parietal peritoneum by a process of peritoneo-cutaneous irradiation and a peritoneo-muscular reflex. It had been claimed that the abolition or diminution of the pain by infiltrating the skin over the painful area with novocain supported Mackenzie's theory. Mr. Morley had repeated these experiments, and in two cases with perforated duodenal ulcer and right shoulder-tip pain showed how the infiltration of novocain really blocked the peritoneo-cutaneous irradiation. The splanchnic nerves were certainly not the afferent nerves concerned in these two cases, but the phrenic nerves. The speaker demonstrated clearly, by means of radiograms of a patient with a gastric ulcer, taken in different positions, that the tender points corresponded to the altering position of the ulcer.

Dr. E. P. Poulton remarked that the term "tone" had caused confusion, and he pointed out that at Cannon's tonus ring the tension of the muscle was lower than elsewhere. He described experiments on oesophageal sensations which proved that pain was due to stretching and deformity of the nerve endings in the walls of the viscus. When pain was produced by inserting a bag containing air into the oesophagus, the pain was diminished either by increase in posture of the organ or by systolic contraction. Though the tension of the muscle was increased during systole, the tension on the nerve endings was less, since the diameter of the viscus was less. If the bag could not be moved down the oesophagus by the contraction, the pain became worse during diastole. Further experiments with an incompressible bag showed that at two points in the cycle of peristalsis was there increased pain—one at the beginning of systole, when the oesophagus was contracted above the incompressible bag, and, secondly, at the end of systole, when the stretching of the wall of the oesophagus by the bag was re-established. Dr. Poulton did not agree with Dr. Mayo that there were local painful areas in peptic ulceration, but that the whole wall was concerned. Dr. Arthur F. Hurst attributed visceral pain to tension. The normal physiological action of a hollow viscus was alteration in tension in its walls; increase of this tension produced fullness, and, if intense, pain. Localization of pain in the mobile abdominal viscera was not accurate; there was no corresponding moving of position of the pain if the viscus was displaced in or from the abdomen. Localization of pain in gall-bladder disease and in appendicitis was constant, even though the gall-bladder might be displaced downwards by enlargement of the liver or the appendix be in the pelvis. Dr. Hurst referred to the situation of the pain associated with tension of the pyloric sphincter in gastric or duodenal ulceration, or reflexly from the gall-bladder and appendix, and described the situations of the pain in tension of the duodenal bulb and whole stomach. Dr. J. A. Ryle reported observations on colonic pain. The pain of a disease affecting a hollow viscus was experienced in that viscus, and was a function of its musculature. Visceral pain could be localized with considerable accuracy. Referred somatic signs and symptoms were usually absent when inflammation or severe mechanical stress was absent. Abnormal degrees of tonic shortening or hardening were not the sole or usual cause of pain in hollow organs. There were other stresses which would increase the tension in plain muscle fibre and so produce pain. Mr. V. Zachary Cope alluded to referred testicular pain in appendicitis. He said that referred shoulder pain was classified as occurring in three areas: pain below the clavicle; pain over the acromio-clavicular joint; and pain over the supraspinatus. These three areas corresponded with the anterior, middle, and posterior portions of the diaphragm respectively. Several interesting cases were quoted illustrating these points. The parietes gave accurate localizations for both fixed and unfixed organs. The pelvis and the portion of the posterior abdominal wall were the silent areas, the remaining portions of the cavity being supplied by the somatic nerves. The spontaneous pain in appendicitis was referred and the deep pressure tenderness was localized. Professor A. W. Sheen (Cardiff) considered the objective more important than the subjective symptoms. Dr. A. W. Cawadias said that some of the cases of abdominal pain might be due to splanchnic neuritis.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

Thursday, July 25th.

Placenta Praevia.

Dr. C. E. Douglas, a Vice-President of this Section, occupied the chair during the second session, and expressed his gratification at the honour thus conferred on a country practitioner. The increasing concentration on the prevention of disease, he said, applied as much to obstetrics as to other branches of medicine; but placenta praevia would always be with them until someone discovered why the ovum became fixed in the lower uterine segment instead of in the fundus. Dr. Bethel Solomons (Dublin) thought it absolutely necessary to insist that placenta praevia could only occur from the twenty-eighth week onwards; any haemorrhage before that period must be grouped under the heading "miscarriage." He classified the varieties of location of the placenta as: (1) central or total placenta praevia, where the placenta covered the internal os completely; (2) partial, where the os was not covered, but the edge of the placenta could be felt just above the internal os in the lower uterine segment. There were various theories to account for the causation of placenta praevia: in the basal theory the ovum had to seek a healthy endometrium in the lower segment; in the capsularis theory the ovum had to spread. In support of the theory that unhealthy endometrium was to blame, he claimed that curettage two months after a placenta praevia labour would prevent the complication in future labours. In diagnosis, the first symptom which should arouse suspicion was fresh haemorrhage accompanied by clots. Bleeding might be extremely insidious in its onset: it was entirely unaccompanied by pain. Bleeding might be slight and recurrent, or the first haemorrhage might be so severe as to cause grave constitutional disturbances, even death. In the emergency practice of the general practitioner to combat the first shock nothing could compare with the infusion

of two pints of saline under the breasts. Examination of the abdomen would show that the uterus was soft and painless, that the presenting part was high and unfixed, and that a uterine souffle was heard in the hypogastrium. These cardinal facts suggested the diagnosis, but it could only be confirmed by vaginal examination, when the characteristic feeling of the placenta could not be missed. Dr. Solomons discussed the differential diagnosis from other possible causes of haemorrhage. He regarded the prognosis in a case which had been correctly diagnosed and treated as excellent. Dr. F. HAMILTON LACEY (Manchester) discussed treatment and reviewed the statistics of the last ten years (1919–28) at St. Mary's Hospital, Manchester. Rupture of the membranes had been carried out in 126 cases, with a maternal mortality of 2.3 per cent., and a foetal mortality of 45 per cent. In 76 cases no active treatment was adopted: maternal deaths in this series were 2.6 per cent., and stillbirths 30 per cent. Version had been performed in 273 cases, with a maternal mortality of 7.6 per cent. and a foetal mortality of 81 per cent. The results showed that version with immediate extraction gave very bad results. In 21 cases of breech presentation a leg had been brought down and labour allowed to terminate naturally with no maternal deaths. Caesarean section had been performed in 33 cases. The maternal death rate in this series had been 6 per cent. and the stillbirths 13 per cent. Fifteen cases had been treated by induction with no maternal deaths, and a foetal mortality of 70 per cent. In 11 cases Willett's method of fixing a weight to the foetal scalp by means of a vulsellum had been tried: the maternal mortality was *nil* and the stillbirths had been at the rate of 27 per cent. Summing up, Dr. Lacey added that as haemorrhage, shock, and sepsis were the commonest causes of death, it was better to empty the uterus soon, when the patient was in good condition, than to temporize. He thought that in the case of central placenta praevia there might be scope for a slightly higher proportion of Caesarean sections, especially where the foetus was alive and near full term. As 75 per cent. of the children were premature, mortality must be very high whatever treatment was adopted. Professor ESSEN MÖLLER (Lund, Sweden) said that their aim should be to treat at the time when the interests of mother and child were common. Caesarean section should be performed more often than at present. Dr. J. W. G. H. RIDDEL (Plymouth) remarked that it was obvious from the paper that the figures for version were extremely bad, whereas Caesarean section gave much better results, at or near term, for both mother and child. It was essential to get cases early, and he was fortunate in his district in getting most of his cases in good time. Dr. L. C. RIVETT was very glad that the Master of the Rotunda Hospital had been emphatic on the question of nomenclature. He asked why, if placenta praevia only occurred once in an individual, it should be necessary to cuiette to prevent its recurrence. He commented upon the high mortality in version, which he did not favour himself: most patients would deliver themselves after such a simple procedure as rupture of the membranes or the use of Willett's forceps. The severe cases of central placenta should invariably be treated by Caesarean section. The condition must be treated as soon as diagnosed. He disapproved of spinal anaesthesia in bad heart cases on account of its effect on the blood pressure. Dr. A. K. MUDALIAR (Madras) pointed out that a placenta which was central before the cervix dilated might become lateral when the cervix began to dilate. The one certain method of diagnosis was by vaginal examination. He had had one or two remarkable instances of difficulty in diagnosing placenta praevia—one such was in a case of vesicular mole. He strongly agreed with the giving of saline solution at once, as soon as the diagnosis was made, owing to the risk of sudden collapse from delayed shock. No mention had been made of administering small doses of pituitary extract—for instance, after performing version and bringing down a leg. He had no experience of recurrence of placenta praevia. He hoped that the impression would not go abroad that the one safe method of treatment in all cases was Caesarean section; there must be absolute justification for operation in the interests of the child, but a central placenta near term was an absolute indication for Caesarean section. Dr. J. P. HEDLEY agreed that Caesarean section had a very limited field of usefulness in placenta praevia. A young woman should take some risk in her first labour to avoid the nervous disturbance experienced in later pregnancies by patients who had once been submitted to Caesarean section. Professor R. W. JOHNSTONE (Edinburgh) raised two points which he wished to emphasize: (1) The importance of diagnosis. There was only one way—that was, actually feeling the placenta. (2) Placenta praevia should never be treated by temporizing. Once the diagnosis was made, treatment must be undertaken there and then. The risk of sudden cataclysmal haemorrhage was too great otherwise. As for Caesarean section, other considerations besides infant mortality must be borne in mind, but he thought its field might be cautiously widened. Dr. GIBBON FITZGIBBON (Dublin) recognized that Caesarean section had a place in the treatment of placenta praevia, but statistics might give a false impression of the frequency with which the operation should be done. At thirty-two weeks it was relatively easy to treat even a primipara by version. Treatment should be available immediately after vaginal examination had been made. When all factors were taken into consideration the statistics of cases treated by version compared very favourably with other methods. It might be justifiable to temporize when bleeding commenced about the thirty-second week and a living child was very anxiously desired. Dr. G. I. STRACHAN (Cardiff) agreed that the term "central placenta praevia" was a relative term. He did not think enough emphasis had been laid on the bearing of the period of gestation upon the line of treatment to be adopted. The interests of the foetus must not be allowed too much prominence. There was an enormous amount of shock connected with these cases, even when the bleeding had not been very great. Blood transfusion had not in his experience given any better results than saline infusion. Dr. R. S. S. STATHAM (Bristol) protested against the too frequent performance of Caesarean section, and the submammary administration of saline. He had seen two cases of sloughing breasts result, so he now recommended injection into the flank. He was against giving hot douches in ante-partum haemorrhage. Treatment should be applied on the spot: patients should not be brought miles over country roads into a large hospital. He spoke favourably of Willett's method, and de Ribes's bag. He had had a case of two Caesarean sections for placenta praevia in the same patient, with a year's interval between operations. Miss MARGARET BASDEN remarked that not much had been said of the treatment of severe haemorrhage by plugging the vagina, which gave very good immediate results, but ulceration or even stenosis of the vagina might occur afterwards. Her alternative method was Caesarean section, with very good results for the mother and fair results for the baby. With regard to the alleged fear in subsequent labours after section, she could see no reason why the next labour should not be allowed to follow a natural course, though she had found that women who had once had Caesarean section performed always pleaded for delivery in that way again.

Professor BLAIR BELL (Liverpool) said that it was necessary to consider every case on its merits. He agreed with those who wished to simplify the anatomical types, and he thought that the correct terms were placenta praevia centralis and placenta praevia partialis—the former to include all examples in which there was encroachment of the maternal os by the placenta. Even well-known authors of textbooks confused the terms "marginal" and "lateral" placenta praevia. Diagnosis and treatment were affected by the position of the placenta, for it might be said that in partial placenta praevia with overlapping by the placenta of merely the edge of the lower uterine segment (so-called "marginal" type) it was often impossible to distinguish the condition from external accidental haemorrhage, and the treatment, so far as delivery was concerned, was the same—usually puncture of the membranes, the administration of pituitary extract, and possibly the application of a tight binder. Professor Blair Bell thought that Dr. Solomons had been meticulous in bringing into the question of differential diagnosis, "erosion" of the cervix and carcinoma of the cervix. All

said and done, the differential diagnosis lay between accidental haemorrhage and placenta praevia partialis. The chief diagnostic points in vaginal palpation were the recognition or otherwise of the placenta through the os uteri, and the fullness or otherwise of fornices with inability to feel the foetal parts. Abdominal palpation revealed malpresentations or failure of the head to engage, owing to position of the placenta, or, on the other hand, a normal presentation and engagement. Another diagnostic point was albuminuria; accidental haemorrhage was often due to toxaemia, and was associated with albuminuria and other toxic manifestations. Placenta praevia might be associated with toxaemia, but this was rare. In many cases Caesarean section was the only proper treatment unless there were grave contraindications such as the condition of the mother or environmental impossibilities. All being equal, placenta praevia centralis, in a primigravida with an undilated cervix, especially when the child was alive and viable, could be properly treated only by Caesarean section. In the remaining cases, if circumstances were propitious, a further considerable percentage of both types of case, when the child was viable, should be treated by Caesarean section. The duration of gestation was, however, an important consideration; while in cases of doubt the mother's life should be the first consideration, in many cases no additional danger to the mother was incurred, whereas by Caesarean section a totally different complexion was placed upon the foetal mortality. The saving of infant life had not, he thought, been adequately taken into account. He warned operators of the danger of post-partum haemorrhage after Caesarean section, as after other modes of delivery with placenta praevia; he had seen two such cases. The accident might be avoided by the use of pituitary extract and ergotin administered every few hours for two days after delivery. He preferred blood transfusion to that of saline. Because of the very high foetal mortality he did not view with favour version as a routine measure in the treatment of these cases; though in multiparae with placenta praevia partialis and careful management it was often—especially outside hospital—the correct line of treatment. Above all, however, it must be remembered that a considerable number of cases, especially those in which the cervix was not involved, terminated by the normal processes of parturition alone. Many cases, no doubt, escaped recognition or were assisted by puncture of the membranes and pituitary extract, which drug, he believed, was extremely useful in the treatment of placenta praevia. Dr. W. R. ADDIS (Manchester) stressed very strongly the need for some simple standard method of treatment; rupture of the membranes, application of a tight binder, and administration of pituitary extract could be employed anywhere. Use of the vulsellum to drag down the child had been made in hospital, but he did not think this a method to commend to the general practitioner. Professor D. DOUGAL (Manchester) thought that "safety first" for the mother should be their motto. There were four methods of compressing the placental site: (1) Plugging with the half breech—but Willett's method—foetal mortality was higher than it should be. (2) the foetal mortality halved. It was not a difficult method to apply, but he was a little doubtful whether it was a safe method to use in the patient's own house. (3) De Ribes's bag was clumsy, and very severe haemorrhage might occur when it came away. (4) Plugging the vagina was very difficult to apply in the patient's house. The classical method of podalic version was the safest and simplest, but he pleaded for the greater use of Willett's method. The indications for Caesarean section were limited to the opportunities of obtaining a living child. Dr. H. L. H. GREER (Belfast) advocated caution in recommending Caesarean section. There was no expectant treatment for placenta praevia; the statistics quoted had answered the question against the justification of routine Caesarean section. As a preliminary to bringing down a leg he always endeavoured to perform external version; much haemorrhage and shock might be caused by internal manipulations. He advocated taking the blood pressure as an aid in diagnosis. He condemned the use of de Ribes's bag: at the time when one wanted to use it in an urgent hurry the rubber was found to have perished. Sir EWEN MACLEAN (Cardiff) quoted Herman's dictum "early version and slow extraction"; he believed this method should by no means be ruled out. He had had one death from post-partum haemorrhage after Caesarean section for placenta praevia; he was not, therefore, personally predisposed to using it in these cases. On the whole the tendency was not to consider the child's life in multiparae so much as one did in a primigravida. The question of having a live child might be of extreme importance, and he thought that more attention would be paid to this in the future. The older methods might often be more fortunate in their results for both mother and child. Dr. E. A. GERRARD (Manchester) suggested that if they could obtain a lower foetal mortality without undue risk to the mother, they should adopt methods to secure this; in this connexion immediate treatment was necessary. Bipolar version gave a foetal mortality of 75 per cent. Dr. C. E. DOUGLAS, Vice-President, thought they had had a mass of very valuable experience from all over the world presented to them. There was evidently still a strong body of informed opinion in favour of version carried out at the proper time. With regard to the diagnosis between accidental hacmorrhage and placenta praevia it was always a good plan to ask a working-class woman when she did her washing. In his limited experience he had waited for the os to admit two fingers and had then turned, brought down a leg, and waited.

Dr. SOLOMONS, in reply, said that plugging of the vagina had been given up at the Rotunda since Dr. FitzGibbon and himself had been Masters. When it had to be used he advised using pledgets of cotton-wool soaked in a very weak antiseptic. He urged strongly that version was the treatment, not version with immediate extraction. Extreme caution was essential in giving pituitary extract, and still greater caution in teaching students that it should be employed. He adhered to his belief in submammary saline injections if given properly. He agreed that giving a douche in ante-partum haemorrhage was bad practice. He thought it safer to bring a patient a short distance to hospital, where she could be given proper nursing attention, than to treat her in her own home. Chloroform was very dangerous in haemorrhage cases; he preferred to use ether. Immediate diagnosis was not always possible if the cervix was closed. It was clear from the discussion that version was a very good method. He had had a modified form of Willett's forceps made for his own use, but thought their application limited to very few cases. He hoped that the warning would go out from that meeting against extraction of the child immediately after version. Dr. LACEY, who closed the discussion, agreed that immediate treatment must be carried out. In cases with shock he gave morphine as well as saline solution. He by no means advocated Caesarean section in all cases. He used strips of lint for plugging the vagina. External version should be employed whenever possible. In about 15 per cent. of these cases the haemorrhage was of the extremely violent type referred to by Dr. Douglas.

SECTION OF DISEASES OF CHILDREN.

Thursday, July 25th.

CHRONIC DYSPEPSIA IN SCHOOL CHILDREN.

DR. E. A. SAUNDERS, a Vice-President of the Section, took the chair, when Professor Frederick LANGMEAD opened a discussion on chronic dyspepsia in children of school age. Professor Langmead defined the usual clinical features of dyspepsia, emphasizing the variability of the signs and symptoms in degree and in proportion. The child was generally vaguely ailing, with an altered appetite, muddy complexion, abdominal pains of differing characters, a poor state of general nutrition, irregular stools, restless sleep, and slight nocturnal fever. The child was often morose, irritable, and solitary in habits. Examination of the abdomen might reveal no physical signs, or occasionally some distension was present with or without faecal accumulation. Dyspepsia in adults resembled the manifestations in childhood more closely than was usually taught. The organic types of dyspepsia were much commoner in adults, but in the present state of knowledge about the precise nature of the functional disturbances of

the stomach and intestines in children it was probably incorrect, he thought, to disregard the stomach in the common dyspepsia of childhood, which was called intestinal. The symptoms of this form of dyspepsia fell into three groups: abdominal, constitutional, and psychical. One line of thought was that the intestinal disturbance came first, leading to the absorption of poisons, and the other troubles followed this. H. C. Cameron, on the other hand, had held that an antecedent acidosis was the cause of the intestinal and nervous symptoms. In Professor Langmead's opinion much more work was necessary in order to settle the question. In the causation of dyspepsia food was undoubtedly important; overfeeding and irregularity in feeding, both as regards quantity and quality, were frequently present. Giving food near bedtime often led to restless sleep, and the bolting of food in excitable children often brought on a sort of "stitch," accompanied by flatulence. Too much roughage in a diet was also a prominent factor in many cases leading to a colitis. Liquid paraffin given too plentifully might also produce colitis. Relative excess of one of the elementary food factors was often not considered sufficiently in the dyspepsias of children of school age; as in the infant, there might be present a disability to deal with carbohydrates and fats. Vitamin deficiency probably played no part in producing dyspepsia at this age period. Defective mastication was another cause of dyspepsia which was often overlooked. There were undoubtedly some cases of entero-colitis due to the dysentery organisms; infection with lamblia might also cause trouble, but with regard to other organisms it was not possible to correlate the symptoms and the course of the dyspepsia with the type of infection, nor was it possible to be sure that the abnormal organisms were not a secondary manifestation. As long as the mucosa remained healthy it seemed to have been shown satisfactorily that stasis and putrefaction could not be the sources of the intoxication. Focal sepsis, such as in the teeth or tonsils, seemed to be concerned, for dyspepsia often cleared up when these foci were dealt with. In the forms of dyspepsia known as hepatic Professor Langmead pointed out that it was the fats which were badly digested, the results being bouts of toxaemia, greasy stools, and slight jaundice. Liver function tests did not give much information in these cases. In fatal cases of cyclical vomiting advanced fatty changes in the liver were found, and there were cases which resembled cyclical vomiting in every respect, except that vomiting was absent. All other symptoms occurred, and the liver certainly seemed to be at fault, although recent work indicated that the mechanism of the bile flow played an important part in the digestive processes. Nervous symptoms were probably secondary to the intestinal upset. Dr. H. CHODAK GREGORY thought that gastric dyspepsia was less frequent in children, possibly because the young animal would vomit so readily. Professor Taillens had recently stated that hyperchlorhydria was a prominent cause of dyspepsia in children, but the difficulties of performing fractional test meals in children led to many fallacies; the fact that rest in bed and the administration of alkalis often cured the condition was not a direct proof. Appendicitis was not, in the speaker's opinion, a common cause of chronic dyspeptic symptoms, but tuberculosis of the mesenteric glands did account for some cases with rather vague disorders. While the dangers of high fat diets had rightly been emphasized, there was the opposite danger of cutting out so much of the fatty foodstuffs that general nutrition and resistance suffered. It was important to maintain a balanced diet, and in particular to ascertain just what sort of fat indigestion was present. The common types of dyspepsia in children were functional, and the system chiefly involved was the nervous system; hence, it was important to study carefully the child's surroundings, and to correct any maladjustment to environment. Mr. HERBERT RAYNER (Manchester) alluded to certain organic lesions in children which produced dyspepsia. In many cases of appendicitis in later life symptoms could be traced back to the later years of childhood. In some cases of acute appendix trouble in children there was a history of recurrent attacks of pain in the abdomen, lasting a few hours, and rarely associated with vomiting. Such attacks ceased on removal of the appendix, which showed evidence of previous inflammation. In another group there had been definite attacks of mild appendicitis, sometimes with perfect health between the attacks, but often with definite deterioration in health and delayed development. Tuberculous glands in the right iliac fossa became important from a surgical point of view when secondary effects were produced, but they often remained quite quiescent. Finally, Mr. Rayner mentioned that the surgeon was not uncommonly called to cases of cyclical vomiting. Mr. S. T. IRWIN (Belfast) dealt especially with duodenal ulcer as a cause of chronic dyspepsia in childhood. The disease certainly occurred in infancy, often with a familial incidence, and, in adults with the complaint, symptoms could often be traced back into the period of school age. Such symptoms included recurrent attacks of pain, sometimes purely nocturnal, and perforation might occur before the diagnosis was established. Mr. Irwin described four cases of duodenal ulcer in some detail, and then went on to discuss symptoms of the pre-ulcer state. It was remarkable how well such patients were; they suffered from discomfort rather than pain until the ulcer actually made its appearance. Vomiting occurring at night without cause and without pain was important, and an excessive appetite was frequently present. Professor C. W. VINING (Leeds) said that the digestive processes in the ordinary child were difficult to upset; it was doubtful whether it was possible to overfeed a child with three meals a day. Nervous influences and environmental conditions were important. He believed that often symptoms classified as dyspeptic really represented a deficiency disease. Protein deficiency was often a cause; he thought children needed more meat than was usually supposed. Dr. J. J. SPIRA discussed the pathology of gastric and duodenal ulceration, emphasizing the differences between the acute and chronic ulcers. Dr. CATHERINE CHISHOLM (Manchester) questioned whether nervous strain at school had much to do with dyspepsia. Out of over 3,500 high-school girls the incidence of any form of constipation, indigestion, diarrhoea, and gastric disturbance was only 4.5 per cent.; even among much poorer children the incidence only rose to 10 per cent. for all forms of dyspepsia. She thought that "feckless mothering" had a lot to do with dyspepsia in children of school age; defective hygiene, including irregular meals and staying up late at night, was an important factor.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

Thursday, July 25th.

ACUTE FOOD POISONING.

PROFESSOR J. CRUICKSHANK (Aberdeen) described the characteristic features of bacterial food poisoning as sudden onset of sickness, vomiting, severe diarrhoea, abdominal pain, and pyrexia. The interval between the taking of infected food and the onset of symptoms varied from two to thirty-six hours. On account of the extremely short incubation period in some cases it had been suggested that the symptoms were due to the presence of preformed toxins, as it was impossible to believe that the viable organisms ingested could proliferate in sufficient numbers to produce such severe symptoms in so short a time. Moreover, in some epidemics the suspected food had been exposed to such temperatures as would have destroyed all vegetative forms of bacteria. Since Gärtner described the organism in food poisoning, great attention had been paid to this or related organisms, and a large group of organisms closely related to the paratyphoid organisms had been described. The one most commonly found in cases of food poisoning was *B. aertrycke*. In a general study of the outbreaks the habits of the people and the sanitary methods, especially methods of slaughter of animals and preparation of food, must also be considered. In many cases the suspected food showed no evidence of deterioration either in colour, taste, or appearance, and often it had been entirely consumed before any suspicion arose, so that none was available for bacteriological examination. A wide variety of foodstuffs were concerned: tinned meat, salmon, sardines, milk, meat, sausages, pork, and mutton; and recently the possibility of infection from eggs had been raised. The only one of these

that seemed to offer suitable conditions for the growth of salmonella was milk, and there was evidence that milk-spread epidemics were widespread and severe. The way in which tinned foods, such as salmon and sardines, became infected was not clear; it was necessary to suppose that, previous to "processing," infection had resulted in some individual tins from some unknown source, and that considerable growth of organisms had occurred, with development of toxins which were resistant to subsequent heating. He had considerable difficulty in following the chain of reasoning put forward to explain those outbreaks when no organism could be found, and which were accounted for by the presence of preformed toxin. The relatively infrequent finding of Gärtner and *B. suipestifer* types was important, as these types were the most frequent exciting agents of disease in cows and pigs; the *B. aertrycke* type, on the other hand, was extremely uncommon in the food diseases of animals, but the most common finding in human outbreaks. He pleaded for a consideration of the possibility that other organisms besides the salmonella might be causative agents. Much interest lay in the production of heat-resistant toxins, and here the evidence was at present conflicting. The clinical aspect presented many points of interest. Although he agreed that in most epidemics of paratyphoid fever the typical signs of food poisoning were absent, in some cases acute symptoms—diarrhoea, sickness, and abdominal pain—had occurred immediately after the ingestion of food, and these could not be dismissed as unimportant. Dr. W. G. SAVAGE (Weston-super-Mare) confined his remarks to the question of food poisoning from preformed toxins. These outbreaks occurred frequently, gave rise to the same clinical picture, and ran the same course. They presented the same negative bacteriological findings, and often occurred with the same kind of food-stuffs. The incubation period was very short (two to four hours), the onset was acute, the symptoms were severe, similar to outbreaks due to living salmonella, but more severe, followed almost always by quick recovery. The foodstuffs responsible were unaltered physically, and free from all pathogenic bacteria; agglutinins were rarely found in the blood, and never in high titre. He thought Professor Cruickshank had magnified the difficulties in accepting outbreaks due to preformed toxin. He had brought forward evidence showing that salmonella did proliferate at an enormous rate on meat foods at warm temperatures, and as the result of personal observation of canning he was quite satisfied that there were ample opportunities for the occasional contamination of a few tins with preformed toxin. He agreed that the experimental proof of the existence of preformed toxins was beset with difficulties. In his experience milk-borne epidemics had not been unusually severe. Mr. P. BRUCE WHITE discussed the botanical question of classification of the food-poisoning bacilli. The known causal organisms belonged to the colon typhoid group, and two genera had been definitely established as causes of acute food poisoning; although relatively rare, the organisms of the Sonne-Flexner dysentery group assuredly did cause some cases clinically indistinguishable from the more usual types of infection by the salmonella group. The importance of the antigenic properties in the classification of this group was then discussed. Dr. W. M. SCOTT spoke of the egg as a possible source of acute food poisoning, particularly in cases of solitary infection. He reported epidemics in which the only possible source of infection was the ducks' eggs used for making whipped cream or custard. It was possible to infect ducks' eggs experimentally with salmonella, and he described the methods by which natural infection of the egg took place. Dr. D. N. NABARRO emphasized the need for considering dysentery infection in what was clinically described as food poisoning, and he related a series of cases presenting the symptoms of acute food poisoning which had been established bacteriologically as dysenteric infection.

BRUCELLA ABORTUS INFECTION IN MAN.

Dr. W. D. CHAMPNEYS read a paper on *Br. abortus* infection in man. He briefly described the history of our knowledge of this disease, and gave a short description of its bacteriology. His main desire was to bring it more conspicuously to the notice of bacteriologists and clinicians, so that if, as was suspected, there were an appreciable number of cases undiagnosed in this country, they might be more readily detected. The number of cases reported on the Continent was steadily increasing, and this was due entirely to more widespread recognition of the disease. Clinically it corresponded closely with *Br. melitensis* infection, and the most useful diagnostic laboratory tests were haemoculture, inoculation of a guinea-pig with blood intraperitoneally, and an agglutination test; a titre of 1 in 80 was sufficient for diagnostic purposes. Dr. G. R. ROSS (Rhodesia) said that in Rhodesia they had definitely established that the prominent type of undulant fever was due to *Br. abortus*. In diagnosis haemoculture was most important, but the organisms frequently required long incubation to show up, and at least fourteen days' observation was necessary before the cultures were discarded. Agglutination tests were so far indecisive, as the serum of a patient suffering from a *Br. melitensis* infection reacted similarly. Dr. PARRY MORGAN (Cardiff) had met with four cases of brucella infection, all of which would have been missed but for laboratory investigations. Of 46 bloods examined for enteric fever 2 showed agglutination of 1 in 250, and both were cases of undulant fever. Of 1,325 cases of blood sent for the Wassermann reaction 5 showed doubtful agglutination of 1 in 40. The milk of infected cows showed distinct agglutination up to 1 in 500; the opacity of the diluted milk did not interfere with the reading. Dr. W. G. SAVAGE (Weston-super-Mare) reported the summarized results of experimental infection of monkeys by Professor Meyer of California.

SECTION OF OPHTHALMOLOGY.

Thursday, July 25th.

A MODIFIED FORM OF LAGRANGE'S OPERATION.

THE second day of this Section was devoted to the reading of short papers. The first speaker, Mr. W. H. KIEP (Bradford), described a modification of Lagrange's operation, which consisted of a thickened flap of conjunctiva reflected down to within about 2 mm. of the limbus, a furrow being cut in the sclera. Into the furrow a keratome was introduced to make the incision, and the part of the anterior lip of the wound was excised. A peripheral iridectomy was now performed and the wound in the conjunctiva was closed with a suture. The advantages claimed were simplicity and diminished liability to late infection. Mr. W. B. INGLIS POLLOCK (Glasgow) agreed with the previous speaker as regards the advantages of the Lagrange operation; the risks of a conjunctival fistula were far less, and the end-results superior. He preferred a Graefe knife to a keratome. Mr. A. BERNARD CRIDLAND (Wolverhampton) thought the Lagrange operation the best in chronic glaucoma. He advised waiting to operate until the tension was reduced to about 40 mm. His experience was that late infection in these operations was extremely rare. Mr. A. F. MACCALLAN thought late infection was generally due to focal sepsis. Mr. H. H. MCNABB (Manchester) quoted a case of late infection in Elliot's operation. Mr. E. E. MADDOX (Bournemouth) asked if the opener had experienced any difficulty in excising the scleral tissue in the operation described by him. He mentioned two modifications of Lagrange's operation. Dr. A. NELL (Colombo) supported the view of the advantages of Lagrange's operation. Mr. J. GRAY CLEGG (Manchester) had seen very few late infections after Elliot's operation, and thought the chances of healing of the sclerostomy were greater in Lagrange's operation. Mr. KIEP, replying, said he did not agree with a posterior sclerotomy, but always used intravenous injections of saline solution, since he had found them more efficacious in reducing the ocular tension.

MINOR INJURIES OF THE EYE IN INDUSTRY.

Mr. A. BERNARD CRIDLAND (Wolverhampton), in a paper on minor injuries of the eye in industry, pointed out that there had been a steady increase in these accidents reported during the last twenty years. The various occupations which caused them and their varieties were described. It was shown that protective measures were not used in 70 per cent. of the cases. The loss of time to the workman

was estimated to be on the average one day's work for every three of these minor injuries. Protective measures were fully described, and various forms of goggles were shown to the meeting. Mr. BISHOP HARMAN commented on the large number of minor accidents, and said the types of goggles were by no means ideal in many respects. Mr. AUBREY JONES (Tunstall) mentioned the number of accidents in coal mines and the potteries, and thought the employers were not very enthusiastic with regard to the use of protective measures. He dwelt on the large amount of time lost by workers on account of these minor accidents. Mr. TUDOR JONES (Cardiff) discussed the question of miners wearing spectacles when working in the coal mines. Mr. BICKERTON thought that insurance companies should be approached as regards the premiums in these cases where protectors had been used.

VITREOUS OPACITIES: SENILE BLINDNESS.

Dr. T. L. DE COURCY (Liverpool) read a paper on the significance of vitreous opacities. He described the development of the vitreous and its structure in the adult. The causation of opacities was stated to be due to the condition of the blood vessels, the blood itself, and vestigial remains. It was shown that in a series of patients 37 per cent. had vitreous opacities; the methods of examination were detailed. The causation of asteroid bodies was discussed, and its treatment. Mr. MACCALLAN also described vitreous opacities due to focal sepsis.

Mr. J. JAMESON EVANS (Birmingham), in a paper on blindness in old age, detailed the provisions of the Blind Persons Act. It was shown that the number of these cases was rapidly increasing. The various causes of blindness in old persons were described; of these cataract was the most frequent.

Mr. BISHOP HARMAN discussed the cause of blindness in old persons, and said his figures showed the largest number to be due to macular degeneration. He did not agree that a hard-and-fast rule as regards the definition of blindness was necessary. Mr. J. G. CLEGG (Manchester) asked if it was obligatory for blind people with cataract to undergo an operation. Dr. H. CAIGER stated his experience in these cases and his methods of filling in the certificate. Dr. F. C. B. GITTINGS discussed the remuneration for granting these certificates.

SECTION OF ANAESTHETICS.

Thursday, July 25th.

THE President of the Section, Dr. A. L. FLEMMING (Bristol), in opening the proceedings, referred to the serious blow which had been dealt to anaesthesia by the untimely death of Dr. S. R. Wilson, who, by his work in Manchester, had set such a high standard to those who followed him. Dr. Flemming believed that the considerable advances in anaesthesia during recent years were very largely due to two factors: (1) the freer interchange of views between workers in widely separated centres; (2) the greater interest taken by surgeons in the endeavours of the anaesthetist. Co-operation between the surgeon and the anaesthetist was becoming more and more necessary. The key to many of their problems was held by the autonomic nervous system, and the greater appreciation of reflex phenomena might result in modifications of technique which would reduce anaesthetic and surgical risks to a minimum.

ETHYLENE AND OXYGEN ANAESTHESIAS.

Dr. H. P. FAIRLIE (Glasgow), in a paper on ethylene anaesthesia, said it could justly occupy a place among the regular methods of anaesthesia. If due care were taken to avoid cyanosis it was a safe anaesthetic. In the results obtained ethylene and oxygen closely resembled N_2O and oxygen; but there were two important differences. Ethylene produced a more profound anaesthesia, and was thereby rendered applicable to a wider range of operations. The second difference, an unfavourable one, was its unpleasant odour, not so much from the patient's point of view as for those who were working near it. The induction of anaesthesia was quite pleasant, though preliminary medication with morphine and hyoscine was desirable. The gas was rapid in its action and excretion, and after-effects as a rule were negligible. From the surgeon's point of view the main criticism lay in lack of muscular relaxation, and haemorrhage. In operations where neither of these was of serious moment ethylene was adequate. The anaesthetist was working within fairly wide limits of safety, and ample warning of danger was always given by cyanosis. The gas could be given by means of any good gas and oxygen apparatus. Ethylene was very inflammable, and great care was needed in handling it. If rigid precautions were taken, however, he could see no reason why it should not be used. For many cases he considered it to be the anaesthetic of choice. Dr. K. B. PINSON (Manchester) referred to his experience of ethylene in dental work. In some cases where N_2O had failed to produce satisfactory anaesthesia, ethylene had been successful. The considerable amount of oxygen which could be given with it rendered it safer in some cases than N_2O. The one thing against it was its inflammability. The ignition point of ethylene and oxygen was very low. Dr. C. F. HADFIELD drew attention to the valuable work done by Professor H. B. Dixon at Manchester University on the ignition points of anaesthetic mixtures. The explosibility of ethylene had been specially studied. It was important to notice that nitrous oxide in some cases would support the combustion of these gases at a lower temperature than oxygen. He also drew attention to the smell of ethylene, which had been proved to be intrinsically that of ethylene, and not the odour of contained impurities.

GAS-OXYGEN IN MIDWIFERY.

Dr. H. E. G. BOYLE, in a paper on gas-oxygen anaesthesia in midwifery, said that the idea that the pregnant woman stood chloroform well was wrong. There had been a number of fatalities in the past, and they would continue so long as this method was employed. In his opinion a better plan was the administration of gas and oxygen for childbirth. He expressed his indebtedness to Dr. Wesly Bourne of Montreal for his introduction to the method. Gas and oxygen, being non-toxic, could be given for a very long time without harm to mother or child, provided always that cyanosis was never allowed to be present. The patient was given enough gas and oxygen with each pain to render her analgesic. Between pains she was conscious. For the birth of the head anaesthesia was produced by the addition of a little ether, and then a mixture of CO_2 and oxygen was given as a respiratory stimulant, and the mother and child were rapidly brought round. The anaesthesia could again be deepened if necessary for the birth of the placenta. He preferred to start the anaesthetic at the beginning of the second stage of labour, but with a nervous patient it could be begun earlier. Disadvantages were: (1) the anaesthetic was naturally more costly; (2) a special anaesthetist must be present; (3) a suitable apparatus must be obtained. The speaker's impression was that the pains, if anything, were increased in force and frequency; the patients were far less exhausted afterwards. He was convinced that the adoption of this method would result in the saving of a certain number of lives—both mother and child. Dr. FALKNER HILL (Manchester) criticized the method on the ground of expense. He thought that chloroform in small quantities was quite an adequate anaesthetic, and was of particular use when a labour had to be conducted single-handed. He had used the Vernon Harcourt inhaler with success.

THE EMPLOYMENT OF GLUCOSE.

Dr. F. P. DE CAUX discussed the use of glucose, chiefly as an antidote to the shock of operation and anaesthesia. He outlined McDonagh's theory of electrical and other changes in the body protein, and in terms of this theory dealt with the nature and treatment of shock, the preparation of patients for anaesthetics, and their post-anaesthetic treatment. As regards acute shock, the main consideration was to give enough glucose at once. The only drawback to a large dose was the risk of subsequent thrombosis; this could be combated by giving insulin or "Sup. 36," which should be injected on the first sign of recovery. Oxygen, when injected subcutaneously, acted like glucose,

but was not so potent; it could, however, be used in mild cases of shock. Purgation and starvation before operation were to be condemned, as they exhausted the glycogen reserve in the liver—the patient's natural defence against shock. The uses of glucose at operations were summarized as follows. (1) Always give glucose before a severe operation: when the liver efficiency was suspected; when the metabolic rate was high; and when the patient was undernourished or emaciated. (2) After a severe operation give glucose when blood transfusion was impossible. (3) It should be employed also after any anaesthetic: where loss of blood had been heavy and blood transfusion was not practicable; when the patient showed signs of shock; where glucose had not been given before the anaesthetic; where a rough surgeon had operated, or where more than the usual quantity of anaesthetic had been used; and where there was a history of epilepsy. The President said he was gratified that there was a really rational explanation for the use of glucose, the value of which everyone recognized. Drs. Hill, Mott, and Fairlie joined in the subsequent discussion, and Dr. de Caux replied.

Rectal Ether Oil Anaesthesia and Brain Surgery.

Dr. Winifred Wood (Edinburgh), in a paper on this subject, said that the uses of rectal ether oil anaesthesia in general surgery were wide, and its safety had made it the anaesthetic of choice in all bad surgical risks in her practice. It was particularly valuable in all operations which imposed a prolonged strain on the patient. In brain surgery it had several advantages: (1) access to the patient's face was rendered unnecessary; (2) the dose of ether was comparatively small; (3) the anaesthetist had time to take observations and chart them. Dr. Wood described the technique of its administration and the preparation of the patient. Rectal anaesthesia was a controlled anaesthesia. It was her custom to supplement the rectal ether with intrapharyngeal ether vapour, this being the most convenient method in brain operations. The type of anaesthesia produced was very light, sometimes amounting only to an analgesia. The breathing remained quiet throughout, and there was very little interference with metabolism, which in this type of case was very important. She had never seen any respiratory complications, even in elderly patients. Dr. A. B. Clery (Dublin) reported a series of nearly 100 cases in which he had used rectal ether. Gwathmey's technique had been followed, and local anaesthesia with novocain had been used in addition. He was well satisfied with the results. Dr. C. F. Hadfield mentioned the difficulty of adopting an elaborate technique in hospital practice. There was passive resistance on the part of the ward staff, which usually led to the gradual dropping of such a method as this. Dr. Coogan, Dr. Ross Mackenzie, and Dr. Boyle also took part in the discussion, and Dr. Wood briefly replied.

The Scientific Administration of Anaesthetics.

Dr. S. T. Rowling (Leeds) read a paper on the scientific administration of anaesthetics, embodying a series of investigations which had been carried out in collaboration with other departments, the object of which had been to place anaesthetics on a definite scientific basis. He described a new type of inhaler and anaesthetic table, the use of which enabled the exact percentages of ether, gas, and oxygen which were being given to be read off at a glance. The importance of anoxaemia was emphasized; the oxygen content of the anaesthetic atmosphere was always reduced, notably in closed, but also in open methods of administration. Carbon dioxide was of the very greatest importance during the administration; it was the natural physiological stimulant of both respiration and circulation. Oxygen and CO_2 must be available in order to give anaesthetics with safety and precision. The speaker described the correct methods of preventing dangers on the operating table, and stressed the importance of rapid elimination of the anaesthetic with a rapid return of reflexes. By means of this new method it was possible to administer an anaesthetic which was pleasant from the patient's point of view, which relieved the anaesthetist of anxiety, and which gave the surgeon perfect muscular relaxation.

SECTIONS OF RADIOLOGY AND DERMATOLOGY.

Thursday, July 25th.

X Rays and the Healing of Wounds.

After making some introductory remarks, Dr. Lancashire, *President* of the Dermatological Section, read a paper on the *x*-ray treatment of wounds, by Professor Freund of Vienna, who was unfortunately unable to be present. Although the rationale of the action of *x* rays was still under discussion, there was no doubt of its beneficent action in sluggish and badly healing wounds, but in the present paper attention was paid to the influence of *x* rays on fresh and open wounds. Professor Freund had begun his work on this subject by employing *x* rays on wounds purposely left open after the excision of tumours in persons liable to keloid formation; the method was subsequently extended to other conditions. He had found the cosmetic results excellent, and in lupus vulgaris and malignant disease the duration of treatment had been considerably shortened. He could cure a patch of lupus vulgaris the size of the palm within six to eight weeks. The total quantity of *x* rays administered was 6 to 7 H. units—rather more than a depilatory dose—and it was spread over six or seven sittings, with intervals of two or three days between. The time of healing was slightly shorter than if no *x* rays were used. If larger doses of *x* rays were given the results were not so good, nor was the prophylactic application of *x* rays before operation so satisfactory. Professor Hauden (Vienna) discussed treatment with and without filters; it was his impression that thick filters had no advantages, and that the best results were obtained with unfiltered rays. He contrasted the practice of surgeons and dermatologists; whereas surgeons preferred a single large dose of rays, dermatologists preferred repeated small doses. Sir Norman Walker (Edinburgh) referred to his experiences in the early days of *x*-ray therapy. He hoped that there would be real co-operation between the dermatologist and radiologist, involving the experience and observation of both. Dr. Ferguson Smith (Glasgow) said that he had had little experience of the exact method of Freund, but that he had often scraped thoroughly cases of lupus vulgaris, followed this up with a chemical caustic, and subsequently given a single pastille dose to the wound, with the happiest results. He considered that excision followed by irradiation was the method of choice in treating keloid. Dr. W. H. Rowden (Leeds) said that the dermatologist should conduct his own *x*-ray work, and take the responsibility for the results. He believed neither in hard rays nor in filtration in dermatological cases. Dr. W. Dyson (Manchester) said that the exact dosage was all-important, and should be suited to the type of cell to be dealt with. Softer rays were indicated for skin cells, harder rays for deeper cells. Dr. Lancashire wound up the discussion, and said that he was tempted to try Freund's methods.

X-Ray Treatment of Skin Infections.

Dr. W. J. S. Bythell (Manchester), *President of the* Radiological Section, then took the chair, and called upon Dr. J. B. Higgins (Manchester) to read his paper on *x*-ray treatment of the commoner microbic diseases of the skin. Dr. Higgins said that he would confine himself for the most part to the methods employed at the Royal Infirmary, Manchester. The theory of the mechanism of *x* rays was very uncertain, but their value was undoubted. The diseases he proposed to discuss were acne vulgaris, sycosis, paronychia, and furunculosis. He always used a 16-inch coil and a Coolidge tube. In acne vulgaris he said that *x*-ray treatment was above all others the method of choice, and he gave details of treatment in thirty-seven consecutive cases. His practice was to begin with three to four half-pastille doses of unfiltered rays, with an interval of seven days between successive doses. Subsequently filtered doses were used. Many variations in dosage were employed by various dermatologists. McKee used quarter-pastille doses of unfiltered rays to the number of sixteen in all, giving one per week, while Artz and Fuchs administered rays filtered through an aluminium screen three or four times only, at intervals for ten to fourteen days. With regard to the rationale of the treatment, he added that one thing was

certain—that it was not due to any bactericidal action by the rays. In sycosis there was a choice of three methods: (1) epilation, (2) stimulation, (3) a combination of the two. He found that his results were very unequal—sometimes unexpectedly good, sometimes disappointing. He always used unfiltered rays. In paronychia and furunculosis the results were not very encouraging. He referred finally to the new work by Eller of New York on supersoft rays in dermatology. This method was still in its infancy, but might ultimately become of importance. Dr. DOUGLAS WEBSTER said that he had had some of his best results in acne with doses only about one-sixth of a pastille, given weekly or fortnightly, even in indurated cases. Fuchs and Conrad of Vienna had claimed good results with doses as small as one-fiftieth of a pastille—almost homœopathic doses—in acne, sycosis, eczema, furunculosis, and psoriasis. As to the quality of radiation, Dr. Higgins had mentioned supersoft rays, but Dr. Webster thought high voltage and heavily filtered rays should be more extensively tried. Dr. F. GARDINER (Edinburgh) said that a dermatologist who treated his cases with x rays needed to be an expert radiologist, and to keep up to date in radiology. He denied that x rays were the method of choice in the treatment of acne, although he admitted their great value. He limited himself to three doses of one-third of a pastille each, at intervals of ten days. He laid stress on the constitutional factor both in acne and in sycosis. In sycosis he used only small stimulating doses. He thought x rays were comparatively useless in paronychia. Dr. CONNELL (Carlisle) also considered that x rays were only an adjunct in the treatment of acne; x rays reduced induration, and facilitated the work of other remedies. Dr. HALDIN-DAVIS said that his own technique was almost the same as Dr. Gardiner's, but that it did not matter how many doses of x rays were given to a patient so long as the intervals were sufficient and no erythema was ever produced. Dr. ELIZABETH HUNT (Liverpool) referred to the importance of gastric analysis in the treatment of acne, and to the general resistance of the skin to infection. Dr. FERGUSON SMITH (Glasgow) had obtained brilliant results from one-sixth pastille doses weekly for twelve weeks. Dr. W. DYSON (Manchester) agreed that small doses were the most valuable in the treatment of acne. Dr. LANCASHIRE, the President of the Dermatological Section, said that, while overdosage might be disastrous, underdosage was useless.

SECTION OF VENEREAL DISEASES.

Thursday, July 25th.

DIAGNOSTIC AND OTHER ERRORS IN VENEREAL DISEASE.

THE President, Mr. W. COATES, took the chair at the second meeting of the Section, when Colonel L. W. HARRISON opened the discussion on errors in connexion with venereal disease. He called attention to the serious mistakes resulting from the failure to examine patients thoroughly, and illustrated his theme by a series of illuminating and dramatic examples. The welfare and happiness of many patients had been sacrificed, because although suffering from gonorrhœa they had been passed as free from it after a single microscopical test or naked-eye examination. The speaker emphasized the necessity of the culture medium being properly made, of the Gram test being adequately carried out; the complement-fixation test ought also to be employed. Attention was directed to the necessity in chronic gonorrhœa of examining the anterior urethra by urethroscopic and other methods. The practice of treating patients as being syphilitic on mere suspicion received well-merited criticism, as did the basing of a diagnosis of syphilis on a "weakly positive" serum reaction, or upon a single positive reaction where the clinical signs were only slightly suspicious. A warning note was uttered as to the tendency to assume that all abnormalities exhibited by patients with positive serum reactions were necessarily syphilitic. Mr. DAVID LEES (Edinburgh) cautioned practitioners against being misled in diagnosis by the social position of patients. He gave examples of pitfalls presented by varicose ulceration of the leg, cervical glandular enlargement, and osteomyelitis. Syphilis must not be diagnosed without every method being utilized. To treat the diagnosis of syphilis lightly was little short of malpraxis. In early suspected lesions provocative injections should not be used until the end of the fourth week. He was impressed by the tendency of tuberculosis to follow upon gonococcal epididymitis. The diagnostic value of urethroscopic examination was vividly shown by cases in which a gonococcal condition was simulated by a urethral polypus, impacted calculus, and fibrous stricture. Mrs. MARGARET ROBKE said that *B. coli* was the commonest infection of all in women, and often resulted from primary intercourse associated with bruising. The symptoms and signs were those of gonorrhœa, but watch must be kept for an acute *B. coli* infection superimposed on gonorrhœa; thus a pyelitis, when it cleared up, might reveal an ordinary gonococcal condition. All complications of gonorrhœa were not gonococcal; tuberculosis of the tubes or a tuberculous arthritis might follow. A weakly positive Wassermann reaction in a toxic pregnancy was not evidence of the presence of syphilis. A strongly positive reaction appeared in some cases of inoperable carcinoma without any history of syphilis, and in some rapidly advancing ulcers of the throat.

Sir ROBERT BOLAM referred to errors in regard to lichen planus, Bazin's disease, and venereal disease. The venereologist must aim at being the perfect physician, and therefore the possessor of a broad outlook. Dr. HENRY GLUCKMANN (Johannesburg) gave examples from his own experience of gonococcal conditions being mistaken for syphilitic ones, and vice versa. A condition of balanitis and a drug eruption was diagnosed as a syphilitic sore and a secondary rash. Dr. G. WHITEHEAD (Manchester) pleaded for the abandonment of diagnosis of early syphilis by the Wassermann test, and showed how satisfaction was expressed by some when such a report was negative. He quoted further cases, and urged practitioners to approach patients with a view to clinical diagnosis in its entirety as a means of lessening error. Dr. ROXBURGH spoke of diagnostic errors brought to his notice in relation to lesions suggestive of syphilis, which were possibly herpetic, and of syphilitic conditions mistaken for eczematous ones. Dr. T. WHEELER HART (Manchester) referred to a case of vulvitis with gross discharge due to disinfectants. He advised the general practitioner to invoke the specialist's advice at an early date. Dr. SELBY PHILIPPSON (Aden) quoted a case in which a marked ulceration of the genitalia produced by the possibly accidental application of potassium permanganate was a source of great diagnostic difficulty. Dr. MURRAY referred to the difficulty of arriving at a correct diagnosis on the part of the general practitioner. Dr. CRITCHLEY asked for information as to the standard of cure in gonorrhœa in the male, and expressed a doubt as to the adequacy of tests at his command. Colonel E. T. BURKE (Manchester) advised practitioners to think of syphilis in all obscure cases, and spoke of the high percentage of fibrous stricture in which the Wassermann reaction was positive. This statement was based on work by Dr. Ross of Liverpool and himself. He warned against overtreatment of the urethra. Dr. V. E. LLOYD referred to the simulation of a gonococcal discharge by diabetic conditions. Colonel HARRISON, in conclusion, commented on the methods employed in making the final test for cure, including, *inter alia*, full dilatation of the urethra by Kollmann's dilator, careful visual examination, the complement-fixation test, and auto-inoculation of the prostatic urethra.

BISMUTH THERAPY IN SYPHILIS.

Dr. SVEND LOMHOLT (Copenhagen), in a paper on the various preparations of bismuth in the therapy of syphilis, stated that practically all syphilologists regarded this metal as a substance superior to mercury. He considered it to be, with few exceptions, more effective and less toxic than the old remedies. Complete cure was attained only after a prolonged course of bismuth therapy, and large quantities of the metal must be introduced, taking care that the resultant bismuth concentration in the organism stopped short of the point of intoxication, but maintained a strong saturation over a long period. The essential aim was to secure uniform and regular absorption of the metal. Internal

and percutaneous administration was ineffectual owing to the restricted and irregular absorption of bismuth. Intravenous treatment was dangerous in large doses, and not sufficiently effective in well-tolerated doses; it was impracticable, since it required frequent injections. Intramuscular treatment secured a fairly quick, regular, effective saturation of the body, without risk of intoxication. The speaker detailed the ways in which the drug might be administered. The course of routine treatment advised consisted of a series of five or six intravenous injections of 60 to 70 cg. neosalvarsan and bismuth oxychloride in watery suspensions in doses of 15 to 20 cg., in a series of eight to ten intramuscular injections. About eighteen injections of neosalvarsan and 60 of bismuth oxychloride should be spread over a period of two years. The daily dose of bismuth metal was about 0.5 mg. per kilo of body weight. The result of treating 152 patients suffering from recently acquired syphilis was as follows: no clinical relapse was seen during or after treatment; no woman gave birth to a child with congenital syphilis; at the end of treatment 2 patients showed a positive Wassermann reaction, 7 a doubtful reaction, and 143 a definitely negative one.

Dr. V. E. Lloyd asked if there were any measures—such as massage, counter-irritants, thiosinamin—by the use of which the absorption of long-standing deposits of bismuth could be hastened. Would it not be better to use rapidly absorbed preparations at first in order to attain a quick general saturation of the tissues, and then to employ more slowly absorbed ones in order to maintain general tissue reserve? He was inclined to think that in view of the small quantity of bismuth contained in the tissues compared with the large amount excreted it would be well to use a slowly absorbed preparation, when the small quantities entering the circulation would be more easily taken up by the tissues instead of being rapidly excreted. Dr. Morna Rawlins asked what Dr. Lomholt considered the point of intoxication in bismuth therapy. Whereas he regarded the "blue line" as indicative of intensive absorption, she was inclined to regard it as chiefly associated with pyorrhoea. As to pain after intramuscular injections, she thought that it was largely due to the technique employed. She asked if Dr. Lomholt considered that as a patient became saturated with the metal absorption and consequent elimination was slower. If so, when dosage was maintained, or even increased, was there a risk of the bismuth storehouse causing dangerous sequels? Should dosage, therefore, be regulated by elimination? Did Dr. Lomholt know of a method suitable for a venereal diseases clinic of measuring elimination? Was it more advisable to give large doses for a short time, which involved a storing up of the metal, rather than small absorbable doses (if such could be determined) continued over a long period? Mr. David Lees (Edinburgh) asked if the results of animal experiments were applicable to man. He believed that pain after injection was associated with technique. Colonel L. W. Harrison wished to know the maximum amount of bismuth which could safely be given in order to achieve the best effect. In his opinion too small an amount was generally administered. He maintained that deep subcutaneous injections were not particularly painful, and regarded them as safer. He thought that the amount of massage employed after an intramuscular injection should be increased. Colonel E. T. Burke suggested that possibly there was no definite relation between the amount of bismuth elimination and the therapeutic result. He asked for information as to the employment of metallic bismuth alone. Dr. Lomholt agreed that caution must be used in making deductions from animal experiments; he believed the figures he had quoted were applicable to man. He thought that pain after intramuscular injection was to be correlated to the preparation used, although faulty technique might be a causal factor. Colloidal preparations presented a difficult problem. He was inclined to think that their therapeutic effect was less than that of some others. There was less danger of intoxication arising, or being caused, by bismuth than by mercury. It was most necessary to maintain regular absorption. He knew of no method for the estimation of the elimination of bismuth which was suitable for a venereal diseases clinic. Of the metallic bismuth he had had but little experience.

SECTION OF ORTHOPAEDICS.

Thursday, July 25th.

The Treatment of Scoliosis.

Mr. D. McCrae Aitken opened a discussion on the treatment of scoliosis by tracing his endeavours to follow certain fundamental principles based on established anatomical and physiological rules. He considered scoliosis the result of a disturbance of the symmetrical co-ordinate reflex action of muscles controlling posture, producing a twisted asymmetrical body associated with lateral deviation of the spine, asymmetrical kyphosis, and asymmetrical lordosis. To restore the postural balance he aimed at eliminating every extraneous factor which might excite scoliosis, and at re-educating all postural reflexes (including the respiratory) after correcting gross deformities, if possible. He stressed the importance of exercises re-educating and maintaining posture, and urged that they should be of extremely simple type, and should correct breathing and balancing errors during lying, sitting, or walking, and should be practised habitually. He gave an excellent demonstration with a cinematograph of the application of a corrective jacket with the aid of an Abbott frame, by which the deformity was improved and controlled. At the same time, pressure applied in the oblique prominent diameter dramatically encouraged increased antero-posterior chest movements in the flattened thoracic areas. The ultimate test of correction was the freedom and spontaneity of the antero-posterior respiratory expansion in the flattened diameter, together with the reduction of lordosis and an even distribution of the body weight.

Mr. A. S. B. Bankart regarded scoliosis as a deformity of a large compound joint subject to the same contractions as other joints. Faulty attitudes would, if neglected, become fixed, and a return of normal muscular activity was only possible with the help of exercises. If exercise and re-education were impossible the spine would have to be supported. When a contracture was present it was necessary to correct this first by sufficiently drastic measures, and then to restore muscle activity. With regard to the deformity, he considered the spinal disturbance itself as the main feature. If this was corrected the ribs would spontaneously return to their normal positions. It was, unfortunately, impossible to bring effective pressure to bear on the spine through the ribs. Most of the improvement obtained by present forcible methods was a compensatory re-alignment of the spine, but he anticipated that methods of true correction of the contractions would be ultimately evolved. Possibly, as in [illegible]k, the first essential was to exert [illegible] the trunk, using methods sufficient [illegible] It might ultimately be found necessary to turn the lateral into an antero-posterior curve. He suggested that some form of effective skeletal traction might be found possible. Miss Forrester-Brown (Bath) agreed that the restoration and rearrangement of reflex muscle control was as much the prime factor in the cure as its defects were in the causation of scoliosis. Treatment must conform to the same principles as applied to any other contracted joints. Lateral postural curves associated with kypho-lordosis which could be voluntarily corrected by the patient had not, in her experience, gone on to rotation and fixed lateral deviation. The complex group of scoliosis with rotation had been treated by various methods in the cases under her care. Corrective plaster jackets were applied with the lumbar spine always flexed and occasionally the thoracic spine flexed. Recumbency for a long time in the Jansen plaster bed had been beneficial in certain cases. Exercises varied to suit the type of deformity were part of the treatment of all cases. Goldthwait's postural exercises, Klapp's kneeling and crawling, head suspension during walking, were used in order to aid active over-correction of the curve. Accurately fitting braces were helpful in maintaining the correction obtained by other methods, and were used as a supplementary to more vigorous treatment in a large proportion of her cases. The aim of treatment was to produce secondary curves close to the irreducible primary curve, and to restore the body axis to the vertical, and this was possible in most patients who persisted under treatment. Mr. Paul Bernard Roth refused to accept the

analogy of the contracted flexed wrist as applied to scoliosis. In scoliosis the bones were deformed and the muscles not necessarily paretic. He repudiated the advisability of attempts to hold the body in a corrected position by pressure applied to the ribs, and denied the possibility of adaptive change taking place thereby. As one who had been brought up in an atmosphere of gymnastic exercise class work from his earliest youth, he found no flaw in this treatment, which was directed to correcting perverted muscle sense. Force and immobilization were useless in scoliosis. Gymnastic treatment gave results which could not be considered anything but highly satisfactory by the most critical.

Treatment of Torticollis.

Mr. B. Whitchurch Howell, in a paper illustrated by lantern slides, recommended that the treatment of congenital torticollis should start as soon as possible. If begun in the first few days it was followed by early and complete cure. It consisted in regular stretching of the affected side of the neck, and massage of the contracted muscles. In later cases his routine was to tenotomize the sternal head of the muscle by the subcutaneous method, and knead the clavicular fibres thoroughly. Describing his method in detail, he emphasized the technical seriousness of the operation. He recommended immobilization in an over-corrected position by means of plaster-of-Paris for several weeks afterwards. Later, re-education for some weeks was desirable. In all but one of his patients treated in this way complete cure had resulted. He only performed the open operation on incomplete or relapsed cases, or on those in whom other deformities existed. Operation was contra-indicated for bilateral congenital torticollis. The subsequent discussion was directed almost exclusively to the advisability or the reverse of (1) subcutaneous tenotomy of the sterno-mastoid muscle; and (2) post-operative control by plaster-of-Paris or other means. Mr. R. Ollerenshaw (Manchester), although agreeing with most of Mr. Howell's suggestions, differed strongly in one important matter. He was definitely opposed to subcutaneous division of the sterno-mastoid. It was surprising to him that anyone who had performed open division of the muscle and had noticed that the layer of cervical fascia which formed the posterior layer of the muscle was always contracted, forming a tight band behind the muscle, could propose to attempt division of this structure with a blind tenotomy. It was too dangerous if done effectively. For a number of years he had been in the habit of using plaster-of-Paris after the open operation, and no case treated at the Royal Manchester Children's Hospital since 1924 had been subjected to any other form of after-treatment. The plaster, which took in the head, neck, and upper chest, was left in position for six weeks until the deep healing, with lengthened muscle, was complete. After this time active and passive exercises were given daily and a light appliance to maintain over-correction was worn at night.

SECTION OF PUBLIC HEALTH.

Thursday, July 25th.

Maternal Mortality.

The President, Dr. R. Veitch Clark (Manchester), presided over this session. In the absence of Dr. Parlane Kinloch, chief medical officer, Department of Health for Scotland, his paper on maternal mortality was read by Dr. Charlotte Douglas. This paper dealt with a statistical inquiry into the 252 maternal deaths that had occurred in Aberdeen during the ten years 1918-27, which provided a basis for the discussion on this subject. No definite relation had been traced between such mortality and environmental conditions, but contagion undoubtedly played a very important part, the *Streptococcus haemolyticus* being chiefly implicated. A plea was made for an extension of adequate ante-natal services and the development of a new midwifery organization. In such a scheme midwives would conduct all normal deliveries, while medical practitioners would provide ante-natal services and deal with any complications brought to light or occurring during pregnancy. The President said that as a cause of death, if taken in gross numbers, maternity was overshadowed by the great killing diseases, such as cancer, heart disease, and respiratory diseases. But although, fortunately, it did not produce the bulk of deaths represented by these diseases, it was of even greater seriousness, for two reasons. One was the disastrous effect on the surviving relatives, especially the children; the other was the high proportion of deaths among persons "at risk." Calculated as a rate per 1,000 births it would be seen that maternal mortality was three times as great as the mortality from cancer per 1,000 of the population, where the whole population above the age of 25 was "at risk." Dr. Kinloch had shown in his paper that during 1928 there had been 676 maternal deaths in Scotland, giving a rate of 7 per 1,000 births, as against an average of 6.4 for the preceding ten years. Of these 676 deaths, 234, or 2.4 per 1,000 births, were attributed to puerperal sepsis. Dr. Veitch Clark believed that the notification of pyrexia, leading, as it had done, to earlier diagnosis of puerperal sepsis, was bound to have a profound effect on the efficacy of treatment. Mr. Bright Bannister said that owing to recent awakening of public opinion on this subject there appeared to be some danger of panic legislation. He thought it necessary to inform the public that it was a problem which could not be solved in a moment. They must recognize that owing to the cruelty of Nature a certain mortality was inseparable from childbirth, but every nerve should be strained to reduce it to a minimum. The predominance of sepsis as a cause was the most serious aspect of the problem. It was natural to ask, and difficult to answer, the question why sepsis had not been reduced in connexion with midwifery to the extent it had in surgery. But he himself had seen a large number of other acute conditions occurring at the time of parturition and wrongly diagnosed as puerperal sepsis. The onset of labour caused a great lowering of resistance, and the speaker thought that autogenous infection was of much greater importance than some authorities averred. He believed that as many women as possible should be delivered in fully equipped institutions. Professor D. Dougal (Manchester) declared his opinion that with the knowledge and the means already in our possession *maternal mortality could be reduced by* 50 per cent. at a comparatively early date. Dr. A. K. Chalmers (late M.O.H., Glasgow) said that Dr. Kinloch's figures were a further illustration of the value of notification, which had already been proved by the result of the Infectious Diseases (Notification) Act and the Notification of Births Act. Dr. James Young (Edinburgh) spoke as the author of the scheme for an improved maternity service which had now become the policy of the Association. The basis of that scheme, he said, was that every pregnant and parturient woman should be assured of the services of a properly trained and competent midwife, and that the confinement in normal cases, which constituted well over 90 per cent. of the whole, should be in their own homes. He was sure it was a mistake to suppose that the provision of institutional treatment for normal cases would bring about any material improvement. The next essential was the provision of skilled ante-natal supervision by a doctor, so that morbid conditions might be detected and their results anticipated. The whole scheme depended on intimate co-operation between doctor, midwife, and hospital, and it was suggested that this should become an integral part of the national health insurance scheme. The success of such a scheme was assured by the fact that in parts of the country where a similar system was in operation the mortality had been reduced to 1 per 1,000, as against the national rate of 5 per 1,000. He especially commended the results obtained by the East End Maternity Hospital of London, where among both in-patients and out-patients the mortality had been reduced to 0.64 per 1,000. Dr. W. H. F. Oxley described some of the methods which had achieved the success alluded to by Dr. Young, and were attributable to the genius and foresight of the matron of the institution. Puerperal sepsis and eclampsia had become almost unknown in their practice. The only antiseptic used was mercury perchloride, and no gloves were worn. He believed that the abandonment of a certain well-known antiseptic fluid would reduce maternal mortality by 50 per cent. The toxaemias of pregnancy had proved very amenable to treatment. Dr. Harper Murray (Newcastle) also emphasized the dangers of this fluid as a disinfectant.

Professor HENDRY (Glasgow) said the Glasgow figures confirmed those of Aberdeen as to the comparative mortality in the practices of doctors, midwives, and hospitals. The practice of midwives could be improved by insisting on the use of mercurial antiseptics and limiting the number of vaginal examinations. All midwives should have an occasional "refresher" course at a maternity hospital. The higher mortality in the practice of doctors was largely because the patients who called them in were mainly those in whom the risk was greatest—primiparae, those who had previously had difficult labours, and those who demanded the luxury of instrumental delivery under an anaesthetic. Dr. ARTHUR GILES classified maternal deaths as those due to non-intervention and those due to unnecessary intervention. The former group were those which would be reduced by ante-natal examination. Unnecessary intervention was sometimes forced upon the doctor by the exigencies of practice. He might have two cases at the same time miles apart, and be compelled to deliver Mrs. A. by forceps in order to get to Mrs. B. in time. Professor F. E. WYNNE (Sheffield), discussing the subject from the epidemiological point of view, said they were presented with many puzzles. One was why some women escaped when all the factors for infection were apparently present. Another was the difficulty of detecting carriers. In the case of one obvious carrier, who had infected eight patients in succession, the most elaborate bacteriological investigation had failed to reveal the presence of the haemolytic streptococcus. He believed there was evidence that the infection was capable of assuming an epidemic form. Miss IVENS (Liverpool) believed that in any future scheme there should be a service of midwives with sufficient education to enable them to be trained. Such women would not be obtained until proper payment was provided instead of the present inadequate fees. Professor LOWRIE (Belfast) emphasized the importance of blood pressure observations in the prevention of eclampsia. Since these observations had been made in their hospital at Belfast there had been no case for nine years. The President, Dr. VEITCH CLARK, summed up the discussion, and said he welcomed the unanimous desire that had been expressed for cordial co-operation between the public authority and the private practitioner. He wished to lay stress on Professor Dougal's declaration that maternal mortality might be reduced by 50 per cent., but he also felt the urgent need for further research.

SECTION OF TUBERCULOSIS.

Thursday, July 25th.

CONDITIONS SIMULATING PHTHISIS.

AT the second session of the Section, the chair having been taken by Dr. G. LISSANT COX, a Vice-President, Dr. F. G. CHANDLER read a paper on conditions simulating pulmonary tuberculosis, with special reference to pneumonoconiosis and bronchiectasis. The speaker summarized the matter with which he dealt by saying that it was by bacteriological examinations of the sputum and faeces, and by these examinations almost alone, that a diagnosis of pulmonary tuberculosis could be established or excluded. He then described various points which helped in the recognition of the association with pulmonary tuberculosis of pneumonoconiosis, lymphadenoma, syphilis, new growth, bronchiectasis, and mitral stenosis. He noted the difficulties in distinguishing the causes of some serous effusions, and the many aspirations which might be necessary in diagnosing polyserositis. He next enumerated seventeen chronic conditions which might simulate pulmonary tuberculosis, and especially called attention to apical catarrh following such conditions as influenza, to asbestosis, and to bronchiectasis. He pointed out that, owing to the introduction of iodized oil by Sicard and Forestier, it was now possible to prove or exclude bronchiectasis, and to localize it. He thought that the routine to be followed in difficult chest cases should be: a careful history, an exhaustive bacteriological investigation, bronchial injections, x-ray examination, and bronchoscopical investigation. In some cases replacement and thoracoscopy were needed, and in others an exploratory thoracotomy. But bacteriological investigation was of primary importance. Professor F. E. TAYLOR (Manchester) said that the occurrence of apical catarrh should be more widely known. In this condition, unlike tuberculosis, the crepitations were constant, and audible over a wide area. He showed slides to support his opinion that syphilis of the lung was more common than had been supposed. He described a case which appeared to be typical Hodgkin's disease, in which x-ray examination proved the existence of multiple calcified tuberculous glands. Unresolved pneumonia frequently simulated fibroid phthisis. Professor Tylecote was accustomed to regard absolute, intense dullness associated with entire absence of adventitious sounds as very suggestive of neoplasm and against tubercle. Dr. BURTON WOOD devoted his remarks to asbestosis, which was becoming of increasing importance in modern manufacture. He showed slides to demonstrate the coarse, cobwebby appearance in the lungs disclosed in x-ray examination, and contrasted this with the disseminated granular appearance in some cases of pulmonary tuberculosis. Dr. P. HEFFERNAN (Buxton) dealt with the diagnosis of silicosis among the gritstone workers, potters, and refractory brick makers in Derbyshire. He had met with no acute cases of the disease. The symptoms of the chronic form were passive or mechanical—dyspnoea and its sequels. Several patients had haemoptysis. The diagnosis for other forms of chronic fibrosis could only be made by radiography. If a patient became infected with tuberculosis, a rapidly fatal form of this disease usually ensued. But such a conjunction was not always fatal, and an antecedent tuberculosis might be arrested by a mild degree of silica fibrosis. Thus three patients with pulmonary tuberculosis had steadily improved after taking up employment in silica brickworks. Dr. H. G. TRAYER (Manchester) gave the findings in the post-mortem room in seventeen cases out of 306 autopsies in a sanatorium, in which macroscopic evidence of tuberculosis could not be found. Eleven of the patients had died of primary neoplasms of the lung. The attaching of undue weight to a single positive sputum in the midst of a series of negative results was, in Dr. Trayer's opinion, dangerous. He described briefly the symptoms and conditions in the eleven patients; and thought that vital statistics of pulmonary tuberculosis would reach a much higher standard of accuracy if all cases of supposed advanced phthisis in which the bacillus was found were submitted to post-mortem examination. Dr. L. S. T. BURRELL enumerated the causes of non-tuberculous fibrosis of the lung under the headings: occupational, injury or foreign body, empyema, broncho-pneumonia, and healed tuberculosis. He held that it was misleading to classify cases of healed tuberculous disease with active tuberculosis. He emphasized the need for making sure that fibrosis, apparently tuberculous, had not been set up by a foreign body lodged in the bronchus without the knowledge of the patient. Empyema, especially when interlobar, might lead to fibrosis. Broncho-pneumonia was an especially frequent cause. In differential diagnosis failure to find the tubercle bacillus in purulent sputum was strong evidence against tuberculosis. Haemoptysis, even when considerable, could not be taken as certain evidence of tuberculosis. The important point was to decide whether fibrosis was progressive or stationary. In the latter case no treatment was necessary except to relieve symptoms.

SECTION OF OCCUPATIONAL DISEASES.

Thursday, July 25th.

INDUSTRIAL DISEASES AFFECTING THE BLADDER.

AT the second session of the Section the President, Dr. DEARDEN, took the chair, and Dr. THOMAS H. WIGNALL (Manchester) read a paper on the incidence of disease of the bladder in workers with certain chemicals. In an experience extending over thirty years he had met workers who had been employed for fifty years in chemical occupations. In the early years, 1870–80, illnesses were noted among the workers, but not connected with their employment; there was no complete examination, so that the records did not afford help in settling the point whether an illness was occupational or not. From 1920 careful investigations of all cases of illness had been made, and all the employees had been encouraged to seek advice for any symptoms that disturbed them. It was very difficult to define the offending agent owing to the variety of

chemicals and their fumes to which any one worker was exposed. Other difficulties were due to the changing of jobs within the factory, men lapsing from employment, and the presence of men whose previous employments had been blamed for similar effects. Experience accumulated over some years suggested that the notable effects of aniline compounds appeared, if at all, in the urinary tract, and specially the bladder. Mr. J. B. MACALPINE (Manchester) showed some specimens of tumours he had removed from such cases. He also gave a very interesting lantern demonstration on the cystoscopic appearances, diagnosis, and treatment of new growths in the bladder. Dr. ARCHIBALD LEITCH, after much research, had concluded that the effect under discussion was due to a final product in the body which irritated the urinary tract in certain individuals. Professor MATTHEW J. STEWART (Leeds) asked whether inhalation or ingestion was the method of absorption. Dr. VERNON DAVIES asked if any definite pronouncement could be made at present. The PRESIDENT referred to a paper by Dr. Alice Hamilton. Dr. H. F. WATKINS had only seen two cases of affection by aniline compounds (excluding dermatitis) in seventeen years' experience. Dr. WIGNALL, in reply, stated that there undoubtedly seemed to be some correlation between the chemicals and the incidence of the bladder conditions, but the main difficulty was to elucidate which of the many used were culpable, and under what conditions.

METHODS OF DUST REMOVAL.

Mr. L. WARD (Senior Engineering Inspector of Factories, Home Office) gave an instructive and interesting lantern demonstration on mechanical methods of dust removal. He said that the plant should be well designed and efficient, the dust removed as near the point of origin as possible, and the removed dust discharged so as not to blow into other workrooms. The velocity of dust removal and the question of the temperature of air were closely related, so that heating arrangements had quite often to be supplemented after the introduction of improved ventilation. The PRESIDENT also showed some slides illustrating dust prevention in the cotton industry.

CHROME AND ARSENIC DUST IN INDUSTRY.

Dr. E. S. BURT HAMILTON (Manchester) read a paper on chrome and arsenic dust in industry. The chief chromium salts concerned were the sodium and potassium bichromates. The effect on the nasal passages of such dust was to produce devitalized patches, with crusting, and, later, ulceration, leading to perforation of the septum of the nose. There was no pus production, probably owing to antiseptic action of the dust which continued to be inhaled. The perforation of the septum was noted in 20 out of 100 workers; no offensive smell was associated. Arsenic in the form of dust had very similar effects. Dr. DONALD CAMPBELL (St. Helens) spoke on the silicotic lung and its relation to pulmonary fibrosis. He stressed the importance of radiographical study and of examining the sputum.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Wednesday, July 24th.

THE EPILEPSIES.

Professor JUDSON S. BURY (Manchester), President of the Section, took the chair at the first session on July 24th, when Dr. S. A. KINNIER WILSON opened a discussion on the epilepsies. Dr. Wilson said that the complexity of this subject arose from the heterogenous etiology of the condition; its pathology was doubtful, and its therapeutics empirical. Epileptic phenomena showed clinical polymorphism, motor, sensory, psychical, and visceral variants existed. Apart from the seizure itself, there were "pre-seizure" and "post-seizure" disorders to be considered. The aura was a sensation and, therefore, a symptom belonging to the psychical series. Interruption of consciousness might, or might not, accompany epileptic manifestations. The motor content usually consisted of violent convulsive movements, though the entire motor performance might involve little more than mild finger twitchings, or momentary spasms. The sensory elements might constitute practically the whole of an epileptic fit. The visceral components were less significant, and included circulatory, respiratory, vasomotor, vesical, rectal, pupillary, and other phenomena. The post-seizure manifestations might be most varied, ranging from sleep to extreme violence. Twenty-one years of experience had convinced Dr. Wilson that the hereditary factor was persistently overrated, and the personal, or constitutional, factor underrated. The number of cases in which there was no congenital element was far greater than that of those in which such a factor seemed responsible. Experiments had shown that normal animals could be made to develop convulsions without difficulty, and the inheritance factor was not essential in the case of laboratory animals. Two technical procedures were requisite for the production of the convulsive state; the first of these, the humoral factor, might be defined as that component which consisted in the alteration of body fluids and biochemical constituents, and included such mechanical alterations as: (1) increased intracranial pressure and increased permeability of tissues; (2) exogenous noxae, such as convulsants (alcohol, lead, absinthe, thujone, picrotoxin), insulin, foreign proteins, anoxaemia, alkalosis; and (3) endogenous factors, such as endocrine disorders. The second factor concerned the mental mechanism. It had long been known that direct irritation of neural centres could result in the development of unilateral or generalized epileptic attacks. After discussing the occurrence of convulsions and pathological states, Dr. Wilson dealt with the mechanism of the production of epileptic seizures, and remarked that what had already been said implied the existence of three or four determinants, such as increase in pressure of the cerebro-spinal fluid. Dr. Wilson believed that, though it had long been held that evidence of cerebral and general anaemia was more or less discernible at the commencement of the seizure, yet there was not sufficient to show that the fit began with a vasomotor constriction. It was equally conceivable that a neural factor originated the vascular change. Anoxemia might be a contributory factor, but the essence of all epileptic manifestations was neurotic derangement. It was impossible to find one single common factor for the totality of epileptic manifestations, unless the significance of some inherent nervous factor or some functional propensity was allowed. Dr. Wilson concluded with a brief note on the influence of intercurrent conditions in the epileptic state.

Dr. J. J. L. MUSKENS (Amsterdam) considered that it was possible to recognize at least two definite clinical entities among the many forms and varieties that epilepsy might present. (1) *Myoclonic epilepsy.* So long ago as eighty years an English physician, Russell Reynolds, had pointed out the great frequency of minor motor symptoms, particularly myoclonic jerks, in true epilepsy; the observation attracted practically no attention. The condition of "myoclonic epilepsy" consisted of the syndrome of headaches, myoclonic jerks, and myoclonic fits—fits tantamount to genuine epileptic fits—whether these symptoms appeared in rapid succession or only after a lapse of years. In some cases headache might be the only symptom, followed after some years—as many as ten—by myoclonic jerks, while again, after a lapse of years, "fits" appeared. In some cases the development of the complete clinical picture was more rapid, while in others all the symptoms were not present or varied greatly in severity. The observation by Russell Reynolds on the frequency of the minor motor symptoms was accurate, but it was not until later work involving the experimental administration of drugs such as camphor bromide demonstrated in the cat and the dog the close relationship between the tactile and acoustic myoclonic reflex and the complete epileptic fit with the characteristic cry, biting of the tongue, and general convulsion. In the lower animals, as in man, the myoclonic jerks and epileptic fits merged into one another, while in both there appeared the same time of selection for the appearance of fits—namely, the time of transition from sleep to wakefulness or from wakefulness to sleep. When an animal was given a suitable dose of camphor bromide the first toxic symptom was exaggeration of both the tactile and acoustic reflexes. It was a fact recognized

by those in charge of premature infants that should the door bang or some such sudden sharp noise occur all the infants reacted by a sharp shudder. Dr. Muskens had described the intermediate conditions between myoclonic jerks and the classical fit, and had been fortunate enough to obtain graphic tracings of the least severe form of fit yet recorded, associated with slight alteration in consciousness. Experiments seemed to indicate that the loss, or change, of consciousness accompanying a fit was due to the anatomical and physiological connexions between certain centres in the brain stem. Among some 3,000 epileptics he had found several cases where simple syncope was frequent before the appearance of fits, and transitional states between syncope and seizure were occasionally met with. With reference to the exaggerated tactile and acoustic phenomena, experiments on cats had suggested that the reticular portion of the pons and medulla played an important part in the production of both these reflexes. If it was appreciated and admitted that these exaggerated myoclonic reflexes easily and frequently merged into myoclonic or genuine epileptic fits, it seemed probable that this area was associated with the production of the myoclonic epileptic fit. Further experimental work supplied evidence that when an animal was dosed with camphor bromide the irritability of the reticular region of the pons and medulla was increased, and at the same time the irritability of the contralateral motor cortex for faradic currents was also increased. This was a detail which had an important bearing on traumatic epilepsy. When confronted with a patient suffering from headaches only or headaches and myoclonic jerks attention should at once be directed to discovering the cause of this condition of "charge" of which the headaches and "jerks" were the manifestations, and in many cases also hypalgesia of certain zones of the skin. This condition of "charge" might suddenly be seen to disappear under the influence of a series of myoclonic jerks, or a regular epileptic fit, and also by an ample evacuation of the bowels. It was of practical value to ascertain the circumstances under which the patient tended to manifest the symptoms of "charge." Such circumstances could be avoided and the patient put on a most carefully arranged hygienic regime of life. Food, rest, recreation, hours of work, and indeed the whole cycle of life must be provided for. Dr. Muskens protested against the habit of classifying epileptic patients as belonging to two classes: (1) those who did not. Until lately luminal or bromide; (2) those who reacted to this was essentially the attitude of mind of the medical staff of the State Insurance Department in Holland. He insisted emphatically that early and incipient cases should not be given such drugs. Even where definite fits had occurred they could in many cases be prevented and the disorder checked by a definite, exact, hygienic mode of life. Years of experience had convinced him that the danger from the use of such drugs was twofold: (1) the mental faculties of patients deteriorated (certainly repeated fits may, and in the long run did, affect adversely the mental faculties); (2) where the dose of a drug that had been taken over a long period was diminished the dread condition of status epilepticus often appeared. (11) *Traumatic epilepsy in civilian practice.* From this class must be excluded all cases which were based on the history of an injury or fracture of the skull, but of which injury there was no tangible trace. Parents frequently recalled some cranial injury to explain or account for the outbreak of the disorder. Cases in which cranial injury had occurred through a gunshot wound in which the bullet had injured deep structures must also be excluded. On the other hand, those cases were included in which there was no actual bone injury as shown by the *x*-ray examination, but there existed a superficial scar and a history of focal cerebral symptoms appearing immediately after the injury. With this delimitation the number of cases of true traumatic epilepsy shrank considerably; probably only one of 200 cases of epilepsy belonged to this class. Dr. Muskens said he had recorded eleven cases of traumatic epilepsy in his book. In the majority the trauma was in the parietal region and the motor zone was involved; in three cases the trauma was in other parts of the head. This selection of the parietal area was also found to be the rule in traumatic epilepsy occurring after war wounds. All eleven patients had fits, nine had headaches, and in three psychical disturbances were present, but were slight and fugitive in character; in two these were well marked, the patients being heavy and dreamy. Whereas in genuine epilepsy of long standing the motor cortex became hyperexcitable, it would be found that in traumatic epilepsy after many years symptoms of the genuine disorder (quite frequently myoclonic jerks) developed. It seemed, therefore, that whether the disorder was due to the "genuine" disease or whether to injury of the cerebral cortex, the hyperexcitability proceeded either from the cortex to the contralateral ponto-medullary centres, or else from the latter centres to the cortex. In this way, by this interdependence of the cortex and the medullary centres, the identity of the final condition in both disorders found its explanation. In ordinary epilepsy the hyperexcitability was supposed to proceed from the reticular region of the pons and medulla to the contralateral motor area, while in traumatic epilepsy the development of the disorder certainly suggested that the hyperexcitability was transferred to the reticular region from the contralateral motor area, *casu quo* also from the non-motor area. The important question was, What was the type of patient who developed traumatic epilepsy after a cranial injury? From a consideration and careful analysis of his cases it was evident that persons suffering from gastro-intestinal disturbances had a strong predisposition to develop epilepsy following trauma. The arrest of fits that occurred in many cases he believed to be due to the combination of general or hygienic treatment, as indicated for genuine epilepsy and surgical treatment. The best surgical operation, however, in traumatic epilepsy the importance of combining those two lines of treatment could not be too strongly insisted on. The original lesion could but remove one of the conditions which facilitated the development of chronic epilepsy. The original lesion was but the exciting condition; operation might, and did, deal with this, but the fact that the patient had had a certain number of fits postulated a change in the nervous structures. He had come under the law that each epileptic fit makes the next one easier of occurrence, therefore the same careful prophylactic treatment was necessary for this class of patient as for the myoclonic epileptic. The same exact and careful regulation of life as regards food, drink, exercise, rest, fresh air, and habit of life was necessary. Great care must be taken to avoid all gastro-intestinal disturbances, and especially constipation. In such cases it might be necessary to give drugs, but only under careful supervision, and an increase of the dose be only after careful consideration.

Dr. GORDON HOLMES regretted the choice of the title "epilepsies," as though epileptic symptoms might be associated with various organic diseases of the nervous system, the action of poisons of many natures, circulatory disturbances and metabolic changes, as well as occurring apart from any demonstrable alterations in the structure or chemistry of the body. He believed the essential factor was the same in all—a liability of the grey matter of the brain to discharge or react by an epileptic seizure under the influence of physiological or pathological factors. Epilepsy was essentially a cerebral disease, but factors that could influence the activity or nutrition of the grey matter might play a predisposing, or even an exciting, part in the appearance of its phenomena. Such hypotheses as that epilepsy was merely a "metabolic dyscrasia" could only retard advance in knowledge. The investigations of microscopists and the work of Foerster, Penfield, Fay, and others on the nature of local lesions that produced epileptic seizures, promised to throw light on its pathology, but an organ might be normal in structure and abnormal in function. The most promising approach for the clinician was the systematic study of Jacksonian or local epilepsy, as the same physiological processes must underlie it. The speaker had recently emphasized the fact that the positive and negative phenomena observed in local epilepsy might be seen in both major and minor attacks of the so-called idiopathic disease, but some of the most interesting observations bore on the excitation of local seizures by simple physiological processes. Here there could be no question of toxic, metabolic, endocrine, psychical, or other

factors, in which the causation of an epileptic attack was so commonly sought. But of the cortical processes involved in a seizure we must remain ignorant until physiologists taught us more of the nature of cortical activity. Of the various possible factors suggested within recent years the most important were probably the metabolic changes to which Dr. Wilson had referred. Alkalosis, anoxaemia, and excessive hydration favoured attacks, but played, probably, only a subsidiary part by influencing the nutrition and functional activity of nervous elements predisposed to epileptic discharge. Circulatory disturbances were undoubtedly more important, though he could not accept the theory that the epileptic attack was initiated by sudden changes in the cerebral circulation. Since they were ignorant of the nature of the cerebral disturbances that constituted the basis of epilepsy and the means of controlling them, they could only attempt to deal with factors that predisposed to, or excited, seizures. Cortical sedatives must be employed in the majority of cases, though a few patients were undoubtedly better without bromide, luminal, and other such drugs. Of equal importance was the care of the general health and the regulation of the life of the epileptic. The cardinal rules should be to maintain health at as high a level as possible, to place as few restrictions as possible on the epileptic, and to assure that he had a congenial occupation for which he was fitted. Diet had rarely much influence on the frequency of the seizures, but many epileptics did better on mainly vegetarian food. Possibly the ketogenic diet lately suggested, or some modification of it, might prove a valuable accessory in the treatment of some cases at least. Dr. W. Russell Brain spoke of his experimental investigations with thujone carried out with Dr. Riddoch. Thujone was the convulsant constituent of absinthe, and could be obtained from oil of tansy, and was so powerful a convulsant that 1/4 minim administered intravenously would convulse a cat of average size. The observations left no doubt that there were many phenomena in a thujone convulsion which could only be explained in terms of neural excitation. Dr. Brain's own view, based on clinical as well as on physiological experience, was that inhibition and excitation both played a part in producing the symptoms of an epileptic fit. Any part of the nervous system, even the spinal cord, was capable of being the site of a convulsion in certain circumstances; and if such circumstances arose such regional fits bore the physiological stamp or local sign of the motor or postural functions normally served by the excited area. But a characteristic spinal or mid-brain fit was only experimentally elicitable when the higher centres had been removed; from which it appeared that the convulsion in an intact animal was to some extent an integrated reaction, the convulsion discharge of the highest levels controlling or suppressing lower level fits. In Dr. Brain's opinion there had been in some quarters a tendency to overstress the symptomatic character of epilepsy and to minimize the part played by constitutional factors. The family history of epilepsy obtainable in about 30 per cent. of epileptics also pointed to an inherited constitutional abnormality, and the relation between a local cerebral lesion and an inherited predisposition was well shown in patients with a family history of epilepsy who only develop convulsions after acquiring a cerebral lesion. He therefore regarded the majority of epileptics as possessing a constitutional predisposition to convulsions, and many also exhibited some indication of a cerebral lesion which acted as a trigger to the charge. He thought it was established that the average blood cholesterol was lower in epileptics than in normals. It was exceptionally low during status epilepticus and serial epilepsy; it tended to be unstable in the neighbourhood of a fit; in a number of cases (15) a fall had been observed to precede a fit. There was an intimate relationship between cholesterol and the liver, and there was considerable evidence of some form of liver deficiency in epilepsy. Therapeutically there was much more hope of alleviating epilepsy on a large scale if we could discover its underlying basis than if we were compelled to look upon it always as a symptom.

Dr. Donald Core (Manchester) drew attention to treatment and prognosis. It was important to realize that people, otherwise normal, were liable to have isolated fits that symptomatically were epileptic—attacks of sudden loss of consciousness with falling, generalized convulsions, and subsequent coma and sleep. Such people might never have more than one or two such attacks, and this in the entire absence of any treatment. Emotionally uncontrolled, nervous, worrying, introspective young men, patients who were continually skating on the edge of hyperthyroidism with its associated vasomotor instability, were peculiarly liable to epileptic attacks, though these were not typically frequent. Two or three attacks might occur at short intervals, and then the patient go for a prolonged period quite free. Such people, however, conformed to the hyperthyroid type in that their intelligence was above the average and, what was of greater importance, they showed normal constructive intelligence. They were capable of bearing the burden of responsible and increasingly complex organization, for example. Another class of patient in whom epileptic fits were liable to occur showed no such impairment of emotional control. They tended towards mental dullness, and this dullness varied from a slight stupidity, which often escaped notice as such, to a definite dementia. Dr. Core suggested that, clinically, from the point of view of treatment and prognosis, epileptic attacks occurred in three types of people: (1) as isolated incidents in normal individuals; (2) in persons who showed well-marked signs of emotional uncontrol with normal intelligence; (3) in individuals whose constructive intelligence was defective. From the standpoint of symptoms these three groups were one; there was no difference between the attacks in any of them. But from that of treatment they were poles apart, and what might be a proper line to follow in one might be disastrous in the others. The first group required no treatment at all, and the less they were brought into the medical atmosphere the better for them. A thorough examination was desirable to exclude the possibility of gross disease of the central nervous system such as a frontal or a temporosphenoidal tumour and of poisons such as syphilis; but as soon as this had been done the patient should be told not to trouble about the incident. Patients of the second group required emphatic reassurance that the occasional occurrence of an attack had in their case no serious significance, and that it did not imply any tendency to brain deterioration. Such sedative treatment as might be prescribed for the attacks need not be continued for any length of time. In the third group the most important element of treatment was to prevent the patient from looking upon himself as a pariah or an outcast. If the mental dullness was such as to prevent even the semblance of a useful life in the home surroundings, then he should be sent into an epileptic colony, where he would live the life that his companions lived. Dr. Core had found the best results from a combination of bromides with borax and arsenic; this was especially useful in the type of case just discussed. For the emotional type of case where specific treatment need not be prolonged luminal was useful.

Dr. E. L. Fox (Plymouth) spoke on the importance of recognizing the psychogenic origin of idiopathic epilepsy, and instanced the fact that in studying the history of cases of epilepsy the close analogy of the emotional characteristics of the epileptic with those of the hysteric was almost invariably forthcoming. He mentioned cases in which repression was apparently an important factor in the causation of epilepsy, and in which the attacks ceased altogether on the repressed incident being recalled. It was important to recognize the existence of a pre-epileptic condition, which was often to be found in children. Dr. Fox felt that if this state was recognized and treated many cases of epilepsy might be altogether prevented. The epileptic gestures which so frequently ushered in an attack were of value in helping to locate the event which started the epilepsy, and also to the patients in their efforts to resist the oncoming of attacks. He advocated trying to raise the level of the emotional standards in all epileptics, so that they could more readily resist the attacks, until they ceased altogether. Dr. F. A. Pickworth (Birmingham) said that about 10 per cent. of cases in mental hospitals were epileptics, and many more had epileptiform fits. Epileptics showed periods

of mental instability and often became demented. In the work on mental disorder at Birmingham certain highly interesting findings applied also to epileptics. Dr. Pickworth then showed a series of slides demonstrating the presence of sphenoidal sinusitis and infection of the pituitary gland in four cases of epilepsy. He considered that epilepsy might be due to an extension of sepsis from an infected sphenoidal sinus along the course of the carotid artery producing the minute focal areas of brain necrosis often found in epileptics. It was conceivable that organisms or their septic products which obtained access to the carotid sheath might be transmitted along the course of the artery by its pulsations. In support of this were (*a*) the haemorrhagic condition of the pia arachnoid in one case, and (*b*) healed conditions sometimes found as a brown staining of the dura. Of the more intimate association between anoxaemia and epilepsy little was known, but Speransky had shown that by freezing a small area of brain tissue autoneuro-toxins were produced which caused convulsions and death in animals; probably freezing was analogous to the angiospasm, which caused the minute focal areas of destruction found in epileptics, and which he had tried to show might be due to bacterial infection of the vessel walls. Epilepsy might also be due to the extension of sepsis through the pituitary gland to the area of the brain immediately above it. The production of macroscopic changes in the pituitary gland by a sphenoidal sinusitis showed that the quality and quantity of its secretion must suffer. From anatomical considerations the secretion should especially influence that part of the brain with which it first came into contact. This was an area of brain concerned with metabolic processes which were often affected in epilepsy, as indicated by the vasomotor changes before, and the somnolence after, a seizure; the low temperature, and the high temperatures not directly due to muscle effort, the peculiar tolerance of fats and the extraordinary success of a diet consisting almost wholly of fats; the disturbances of acid-base equilibrium; the variable glycosuria and other chemically demonstrable substances in the blood and urine; the abnormal hunger and thirst. Dr. TYLOR FOX (Lingfield) outlined his experiences of a ketogenic diet in five cases of epilepsy. In common with American observers, he had found this diet to be most effective in cases of "petit mal." The patients remained almost free from attacks while the diet was taken, but the fits tended to recur, although with less frequency, when it was discontinued. Dr. Tylor Fox expressed the hope that others who were experimenting with the diet would publish their results. The President, Dr. JUDSON BURY (Manchester), confined his remarks to two problems—namely (1) the occasional spontaneous arrest of the disease, and (2) the influence on epilepsy of intercurrent maladies, such as measles. If it was admitted that the cardinal factor in the epileptic condition was instability of the cerebral neurones, then such cessation of the seizures indicated that the neural mechanism had become more stable. It therefore seemed more probable that such restoration resulted from biochemical changes, rather than vascular or other extraneural factors. In favour of this hypothesis was the fact that benefit resulted from the administration of chemical substances such as bromides and luminal. There was therefore reason for hope that some day a curative remedy would be discovered. A ketogenic diet in association with small doses of the bromides or luminal was said to keep the patient free from seizures. He commented on recent communications by Drs. Gordon and Tylor Fox on the levulose tolerance test for hepatic efficiency for patients with epilepsy, and on the cholesterol content of the blood plasma in which these authors had collaborated with Dr. Russell Brain. The upshot seemed to be that there was a definite liver deficiency in epilepsy which was particularly marked during severe fits. He suggested that it might be worth trying minced liver in the treatment of epileptic patients. The pathology of the disease was so obscure that such a simple variation in diet as this might reasonably be employed. Dr. A. MCDOUGALL (Manchester) spoke of his experiences at the David Lewis Colony regarding the general character and temperament of epileptics.

SECTION OF MEDICAL SOCIOLOGY.

Friday, July 26th.

THE VALUE OF HEALTH PROPAGANDA.

THE subject for discussion in the Section of Medical Sociology, the value of health propaganda, was developed in three opening papers, which are published in this issue of the *Journal* at page 242. Dr. E. K. LE FLEMING, on taking the chair, said that the object of the discussion was to elicit the basic principles underlying health propaganda. The opening papers would deal with the points of view of the medical profession, the administrative officer, the press, and the public. Lord Leverhulme, a Vice-President of the Section, offered friendly criticism of Professor Wynne's statement that vulgarity was an integral part of all successful advertisement. Advertising which was vulgar was not permanently successful. Lord Leverhulme was interested in the difficulties, perhaps unavoidable, in the contribution by medical men of signed articles to newspapers. He referred to the suggestion that those engaged in industry should be medically examined at regular intervals. The difficulties were the expense and the suspicion of many workpeople that the suggestion had ulterior motives. He pleaded for some measure of co-operation between manufacturers and the medical profession in propaganda relating to proprietary articles; and, while recognizing the caution necessary in the profession, reminded his audience that large sums of money were spent by manufacturers in research and experiment, in order to increase the health value of their products. The opening papers were then read by Professor F. E. Wynne (Sheffield), Dr. H. C. JONAS (Barnstaple), Mr. H. A. Gwynne, Editor of the *Morning Post* and President of the Institute of Journalists, and a communication was made by Mrs. E. D. SIMON (Manchester).

Councillor WRIGHT ROBINSON (Manchester) expressed the opinion that more houses were wanted and not more doctors. He thought that health lectures were often more successful, and had more effect, than medical officers of health suspected. He advocated the reading of the health reports of these officers; and he desired further investigation of the food we ate, and the removal of diseased people who prepared it. Only those in the pink of health should assist in food production. He referred to the dermatitis which sometimes occurred in the manufacture of bread; and regretted that while a sum of money up to £200 could be spent on a milkman deprived of his occupation, such compensation could not be given in other trades. Mr. Robinson believed that the best form of propaganda was to be found in the methods of medical inspection of school children. Dr. F. E. FREMANTLE, M.P. (St. Albans), thought that the voluntary societies were an essential part of the health propaganda organization. Not only were they experimenters and forerunners of official activity, but they were a prominent and logical part of the health machinery of the nation, and a preservative against the deadening dangers of bureaucracy. The Central Council for Health Education, with its committee representative of many authorities, its thirty-four voluntary bodies, and its associated members, was a necessary bridge between official and voluntary machinery; and societies such as those dealing with mental welfare, venereal disease, tubercle, cancer, leprosy, midwives, and maternity were doing essential work, supplementing that of official authorities. He hoped that industrial assurance societies would take more part in the work. Dr. R. VEITCH CLARK (Manchester) said that the value of health education lay in enabling people to reach out towards the physical well-being which was essential to full happiness. Health education should not be introduced as a new unit of interest, but should be made part of the daily and monthly life of the people in their organized entertainments and amusements. Thus short public health films should be included in the winter programme of general cinema shows in local societies and among boy scouts, girl guides, and so on. The education given by doctors and nurses in maternity centres, and infant and school clinics, should be extended. Education should be given specially to the young parent, as well as to youth in general. Mr. NICHOLLS (*Manchester Guardian*)

suggested that the chief qualification of the journalist was in knowing "when to put the dope on the spike instead of in the waste-paper basket." What was of value to the newspaper was of value to the public. He thought that the medical profession should consider improvements in its publicity methods. Public health departments were generally of great help to the press.

Dr. H. B. BRACKENBURY explained the position of the General Medical Council, and its discouragement of advertisement, not primarily in the interests of the medical profession, but in those of the public. The point at issue was whether publicity was indulged in for personal advantage and in order to attract patients. Dr. Brackenbury deprecated Mrs. Simon's remarks about the school medical service. There was no antagonism between the service and the medical profession; and it was through the efforts of the British Medical Association that the service was established. But the methods of carrying on the service were often objected to. The best methods of health propaganda were: the public health services, used primarily as educational agencies; the schools, through the teaching of personal hygiene; and the family doctor. Dr. T. WHEELER HART (Stretford) thought that health posters were useful if they were humorous. But propaganda should not be such as to make people over-anxious, lest they should become distressing to themselves and an appalling nuisance to the general practitioner. He criticized the emphasis laid on the infectiousness of tuberculosis, which led to patients being looked upon as worse than lepers. Miss NORAH MARSH (Secretary, National Baby Week Council) pointed out that many of the voluntary child welfare societies were already establishing co-ordination; and instanced the formation of the National Council for Maternity and Child Welfare. Through this body and the Central Council for Health Education, medical officers of health could secure almost any propaganda service. She thought that a system of registration, as advocated by Dr. Wynne, was impracticable under existing legislation.

Dr. A. K. CHALMERS (Glasgow) emphasized the value of home education, and of the opportunity afforded by the Notification of Births Act for reaching the centre of the family circle. With the enormous expansion of housing during recent years, and with the well-known evil effects of bad housing, it was plain that little progress in health could be made while knowledge was confined to the few, and failed to gain the driving power of an educated public opinion. Now that the legislature had seen the need for unifying the administrative authorities concerned with health, the complement of this new epoch was the co-ordination of the many agencies engaged in health propaganda, with an intelligence service to cover the whole field of voluntary effort. Miss OLGA NETHERSOLE (People's League of Health) traversed Dr. Jonas's opinion that the statement, "You cannot run an A1 empire on a C3 population," was based on examination of the residue of civilians left after five million men had been passed A1. She quoted remarks of Sir George Newman, before and during the war, about the existence of not less than a million defective children. She took the optimistic view that a few pounds spent in disseminating knowledge would obviate the expenditure of hundreds of thousands of pounds on defectives, and hazarded the opinion that a very small percentage of our legislators knew how the masses lived. To teach the people scientifically the principles of life which govern health, with the object of getting taxes voted for the support of health, she had founded the People's League of Health. She hoped to see the Royal Colleges of Physicians and Surgeons, the Medical Research Council, and the British Medical Association issuing considered opinions and conclusions for dissemination by the public-education-in-health department of the Ministry of Health. Dr. HELEN BOYLE (Brighton) urged the need for publicity in mental hygiene, since a simple little thing like the mind tended to be overlooked in the presence of such mighty atoms as the appendix, the teeth, and the tonsils. Thus matters such as the admission of voluntary boarders to mental hospitals, agreed, by those who knew, for twenty or thirty years, had not been acted upon, while young offenders were put on probation with no inquiry as to their mental make-up, and recidivists came forty, fifty, or one hundred times into the courts. Dr. CONSTANCE MORTLOCK-BROWN (Devon) aired a local grievance in water supply. All was not well in North Devon; present-day propaganda was useless. She demanded action, and not propaganda.

Dr. T. EUSTACE HILL (Durham) supported the work of voluntary health organizations, which had been largely responsible for the development of health propaganda, and a great stimulus to its progress. He declined to take all of Professor Wynne's statements seriously, and thought that some of them might be described as "stunts" such as Professor Wynne condemned in others. He was convinced of the value of the press in sound health propaganda, and would like to see a committee of representative editors, medical officers of health, and others, which would issue to the public periodically articles of medical and public health interest. Lord LEVERHULME, Professor WYNNE, Dr. JONAS, and Mr. GWYNNE replied briefly on the discussion, and a vote of thanks to Dr. Le Fleming for his skill and courtesy in the control of the meeting was carried by acclamation.

Reviews.

UNIVERSITY COLLEGE, LONDON.

THE centenary of the founding of University College, London, was celebrated three years ago. The history of that institution through the hundred years has now been written by Mr. H. HALE BELLOT, formerly of the Department of History in the College, and now Reader in Modern History in the University of Manchester, and published by the University of London Press. It makes a handsome volume,[1] and includes a considerable number of very interesting illustrations, some of them reproduced from *Punch* and the *Illustrated London News* of past years, vividly recalling the topography and the teaching conditions of the days that are gone. In a pocket of the cover, too, will be found statistical charts of some value, showing the growth of the departments and other matters.

The College, it will be remembered, was first established as the London University, becoming afterwards, as the result of much controversy, a college merely in association with the new university, and now being a constituent part of that university lately reconstituted and reformed. Since the date of Gresham's foundation in the sixteenth century the proposal to establish a university in the metropolis had from time to time been made. Social, industrial, and religious conditions did not, however, become favourable for this till the first quarter of the nineteenth century, and so it fell to Thomas Campbell, who, after a visit to Bonn in 1820, revived the proposal, to have more success than his forerunners. The English universities by the end of the eighteenth century had become the preserve of a section of the community. Social exclusiveness and religious tests forbade them to large numbers whose intellectual activity justified admission. The tests, in particular, led to a movement for the establishment of a Dissenters' University, but it was fortunately on a wider basis than this that the Deed of Settlement of the University of London, 1826, was drawn up. Thomas Campbell first secured the practical assistance of Isaac Lyon Goldsmid, representing the aristocracy of the Jewish race in England. Goldsmid's long association with Brougham brought in the support of the Whigs, the Duke of Norfolk, who spoke for the Catholics, the prominent Dissenters, and, through his association with the Mechanics' Institution, George Birkbeck, together with the Utilitarians represented by Grote, Mill, Tooke, and Warburton. These men formed the bulk of the original council, and entered upon their further struggle for the actual establishment and building of the institution. The first actual appointment made to the professoriate was

[1] *University College, London, 1826–1926.* By H. Hale Bellot, M.A. London University of London Press, Ltd. 1929. (Roy. 8vo, pp. xvi + 464; illustrated. 25s net.)

that of Leonard Horner as Warden. The University actually opened at the beginning of October, 1828. It was not until ten years after the Deed of Settlement that a Charter of Incorporation was granted, and then it was as a University College, and not as a University, that the College was incorporated, a second charter, sealed immediately after the first, establishing the new University of London, empowered to grant degrees in Arts, Laws, and Medicine, after examination, to candidates holding certificates of having completed a course of instruction at University College, King's College, and such other institutions as might thereafter be approved for the purpose.

The volume under review describes in an interesting way, and with relatively full details, the initial struggle for foundation, the start, the early difficulties, disappointments, and quarrels, the depression of the years immediately following upon incorporation, and the revival and triumphs of a time more recent. Separate chapters deal with the admission of women to the College and University, and with the establishment and development of the library. Throughout the volume the medical school necessarily takes a prominent place, since the faculty of medicine has from the beginning been perhaps the most important department of the College. It was the first to begin work, and the expectation of some of the promoters that the reform of medical education would be the most practicable part of their project has been fulfilled. Mr. Bellot, indeed, specifically records that "in its early years the University owed its survival to the success of its medical school." The aim was to replace by systematic instruction and training an empirical and mainly clinical training provided by practising physicians and surgeons. Even so, the course for the diplomas of the Royal College of Surgeons and the Company of Apothecaries was commonly of only fifteen months' duration, but the council consistently recommended a four years' course at least to those who could afford it. Complaint was inevitably made that the number of lectures to be attended was excessive, and that the new school was too expensive. The organization of the several studies in a single school was difficult, and the early history of the medical chairs is very confused. "The delimitation of their several provinces was experimentally determined, and the conflicts which ensued nearly exploded the University." The feuds and recriminations which up to that time were characteristic of physicians, surgeons, and apothecaries as general classes of medical practitioners were abundantly illustrated by those of Bell, Pattison, Bennett, Richard Quain, Elliotson, Cooper, and Liston in particular. The biographical details relating to these men—their characters, qualities, idiosyncrasies, their mutual jealousies and jarrings—will be found set out and described in the fifth chapter of Mr. Bellot's history. William Sharpey, appointed to the chair of anatomy and physiology in 1886, alone appears to have fully justified the choice of the council, both by his own personal fitness and by that adaptability which is required when working as one of a team. The internecine quarrels of the professors were aggravated by their common quarrel with the Warden, Horner; and it was long before a sufficient number were got rid of to produce a relative peace. Later came W. H. Carpenter, G. Viner Ellis, J. E. Erichsen, T. Wharton Jones, and others, remarkably interesting and vivid sketches of whom are to be found in Mr. Bellot's book. These names begin to link up with the student days of many who are still engaged in the active practice of their profession. Such personal connexions, remote though they may be, necessarily add to the interest with which this history of University College will be read: but even those who have not any such connexion, and those who have no personal association with the College at all, will find themselves greatly attracted by much of this story, and will learn from its pages many things of value with regard not only to medical education, but to other branches of collegiate and university work. It is an important contribution to the history of freedom of thought, of the examination of women, of the profession of medicine, and of higher education in all its branches.

RADIOGRAPHY OF THE VERTEBRAE.

The Vertebrae Roentgenologically Considered,[2] by Drs. A. W. GROAGE and R. D. LEONARD, is one of a series of monographic atlases edited by Dr. James T. Case, and is quite up to the high standard of the seven volumes preceding it. The eight chapters into which the book is divided deal successively with general considerations, structural abnormalities of the spine, and pathological conditions of vertebrae, as Part 1. Various sections of the spine are considered in detail in Part 2, and the fifth lumbar vertebra has a chapter all to itself. Illustrating the text there are 203 *x*-ray studies, together with thirteen clinical illustrations and one coloured plate; all are good and adequately fulfil their purpose. There is little to criticize in this work and much to praise: nothing appears to have been omitted. The chapter in which the authors discuss the changes in vertebrae, usually described as due to chronic osteo-arthritis, is very interesting, especially as to the relationship of these changes to trauma. It is considered that the hypertrophic changes—often described as "lipping of vertebrae"—should not be considered as true arthritis, but as due largely to chronologic age changes. The authors are especially strong on the various types of fracture, and their remarks on injuries involving the atlas and axis, and the *x*-ray diagnosis of the same, are a valuable and original contribution to what is often a difficult problem. We would also call attention to what they have to say as regards the post-traumatic disease of vertebrae which Kümmell first described. Another strong feature noticeable throughout the whole work is the lucid and clear manner in which the main points of differential diagnosis are set out. Altogether this is a delightful and instructive book, well printed on good paper, well written, well illustrated, most valuable for reference to all surgeons, more especially those practising orthopaedic surgery, and to all radiologists.

ORTHOPAEDIC SURGERY.

IN *Diseases and Deformities of the Spine and Thorax*[3] Dr. STEINDLER of Iowa offers a serious contribution to the study of deformities. In his preface he expresses a preference for the plan of developing his subject with strong emphasis upon its theoretical and experimental foundation. In dealing with a subject like this, in which there is so much that is even now uncertain, and in the treatment of which principles are apt to be neglected or forgotten, such a foundation is particularly desirable. The human spinal column is such an extremely important structure, and at the same time built up of so many parts and with so many functions, that a recourse to basic principles and facts is necessary if success in treatment is to be attained.

The first chapter is devoted to congenital deformities. These are interesting in themselves and important for their immediate and remote effects; some of these—for example, scoliosis—occupy much attention in later chapters. Static and static constitutional antero-posterior deformities of the spine have of late years occupied a large place in orthopaedic literature, including as they do those anomalies of posture many of which depend more on the neuromuscular regulation of tone than on inherent defects in the spinal column. Scoliosis has long furnished battlefields for warring theories and systems of treatment. In its slighter unprogressive form of no clinical importance whatever and easily dealt with, it is in its more severe and progressive grades an opprobrium chirurgiae—a condition still incurable although capable of relief. Dr. Steindler devotes 118 of his 572 pages to consideration of this subject, and takes up the position that in severe cases compensation should be aimed at when complete correction is unattainable. A deformity having so many varying basic causes cannot, however, be treated by any one method. Fracture and dislocation deformities are, as the author says, matters of secondary consideration in them-

[3] *Diseases and Deformities of the Spine and Thorax.* By Arthur Steindler, M.D., F.A.C.S. London: H. Kimpton. 1929. (7 × 10¼, pp. 573; 76 plates. 52s. 6d. net.)

selves. It is the results of displacement of bone which matter, and sometimes are relieved by operative intervention.

Low back pain, like static deformities, has of late come very much to the front in orthopaedic literature, and has, we think, provided osteopaths and bone-setters with much of their occupation in the past. The increased attention paid to it at the present time will probably diminish the opportunities of irregular practitioners. In this disorder the symptoms are often slight and illusory, and the surgeon must depend to an unusual extent upon patients' statements. It is perhaps surprising to find that, according to Herndon (as quoted by Dr. Steindler), out of 900 cases only 5 per cent. were malingerers. Yet it may be said that in the realm of industrial medicine the best treatment for many cases of low back pain is settlement of claims to compensation. Dr. Steindler describes bone-fixation operations for symptoms attributed to sacro-iliac subluxation, but is not very enthusiastic in recommending them.

Tuberculosis of the spine has been so much investigated and discussed that its treatment, or at least the principles of its treatment, are almost standardized; nevertheless, this work contains a safe guide to its pathology, symptoms, and cure. As to osteomyelitis of the spine, Dr. Steindler realizes that, as recommended by Starr and others for osteomyelitis of the long bones, early diagnosis and drainage is of the first importance. Syphilis, chronic arthritis, and tumours of the spine all have due consideration; their treatment is described, but does not call for comment here. Dr. Steindler is a safe guide to the surgeon in the treatment of spinal lesions and deformities. He is not over-enthusiastic in the recommendation of operative intervention, but takes judicial views of the problems offered, and if his advice is followed the best results may be hoped for in any given case.

HEART DISEASE IN CHILDREN.

THE most recent addition to the Modern Medical Monographs is by Drs. H. B. RUSSELL and C. K. J. HAMILTON, on the important subject of *Heart Disease in Childhood*.[4] It is a compact volume containing much useful information, as, for example, on electro-cardiographic records in children, but at the same time it is disappointing in many places. It is scarcely permissible in a modern monograph to omit all references to the current literature even at the risk of making the book "unduly cumbersome," which is the excuse offered in the preface. Such an omission makes it difficult to explain certain weaknesses in the text on other grounds than that the authors are not too familiar with this literature. No mention is made of Naish's work on rheumatic pneumonia as an explanation of certain signs at the base of the left lung in pericardial effusion (p. 39). The use of adrenaline in heart-block, as advocated by Sutherland, is not mentioned in connexion with this disorder (p. 53), and Cabot's work on the heart should surely be more fully mentioned in connexion with "mitral regurgitation." Indeed, the description of this latter condition is poor; no adequate pathological explanation is offered, and the disorder is described quite separately from dilatation and called "the commonest of all the valvular lesions that are met with in children." In fact, a very weak case is made out for the occurrence of mitral regurgitation as an isolated valvular lesion, and the authors use the term loosely as a mere label for cases of endocarditis unaccompanied by the types of murmurs usually accepted as indicating stenosis. Apart from shortcomings in these respects, which are after all fundamental, the book is good in many details. The description of the evolution of the murmurs in commencing mitral stenosis is excellent, and so also is the section on treatment of compensated endocardial lesions with its insistence on the pulse rate as a guide rather than the murmurs present. The "large" doses of salicylates recommended on page 65, however, are small compared with those advocated and used by some authorities, as, for example, the late David Lees. The bulk of the book is necessarily concerned with rheumatic heart disease, yet in a modern monograph it is surely a deficiency that ulcerative endocarditis is not considered at all, either alone or in its relations to the lesions of the heart in rheumatic fever. The authors have presented a good summary of some of the disorders of the heart in childhood, but the result is rather too superficial to justify the title of a "modern monograph."

NOTES ON BOOKS.

Fundamentals of Objective Psychology,[5] by JOHN FREDERICK DASHIELL, professor of psychology, University of North Carolina, has been written from the standpoint of the behaviouristic school. While the treatment offered in this book is that of consistent objectivism, the writer has not intended to imply an antagonism to the employment of an introspective approach where the teacher wishes to apply it. He explains that some guidance for the study of "self-observing technique" might have been included in this work, but he felt that it was better to let the strictly objective approach stand for itself. The subject-matter is excellently arranged, illustrations and diagrams are numerous, and considerable attention has been given to experimental methods of study. The student of psychology will find this volume thoroughly adequate as an introductory textbook.

DR. CLAES GRILL has produced a well-documented monograph[6] on the acoustic signs used in the diagnosis of lung cavities. The inadequacy of the classical signs in many cases has long been recognized, cavities found at post-mortem examination or radiologically having been overlooked even by skilled diagnosticians. Dr. Grill has attempted in a large number of sanatorium and clinic cases to correlate the physical signs found in the course of the ordinary examination with the *x*-ray appearances. He has, moreover, investigated some of the problems of sound transmission, and related his findings to the mechanical conditions that are present in cases of superficial and deep-lying cavity. From these two methods of investigation he has been able to suggest a useful revision of the physical signs generally held to indicate cavity, and to formulate a differential diagnosis between cavity and pseudo-cavity. The monograph is well printed and illustrated; it is supplied with a good bibliography.

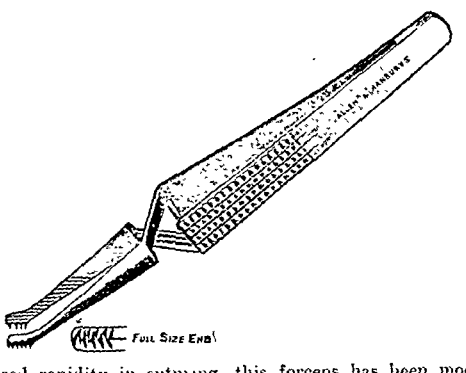
PREPARATIONS AND APPLIANCES.

APPROXIMATING FORCEPS FOR THE SKIN.

MR. A. W. HOLTHUSEN, B.S. (surgeon to the Southend Victoria Hospital), writes: The approximating forceps for the skin designed by the late Mr. C. P. Childe of Portsmouth is of great assistance in avoiding the in-turning of skin edges during suture when completing an operation. It needs, however, the use of one hand in holding the ends together while the stitch is tied. In order to free this hand, and so make for



increased rapidity in suturing, this forceps has been modified by reversing the spring action, so that when the finger grip is released the ends remain in apposition. A certain amount of practice is necessary to get accustomed to the reverse action of the spring, but it will be found that the modified instrument does help in producing a neat and therefore quick-healing scar.

The instrument has been made for me by Messrs. Allen and Hanburys.

HEALTH PROPAGANDA.

Whether the modern hedonistic doctrine which subordinates everything to the pursuit of happiness is the true philosophy of life or not, most people will agree that health is a contributory factor to what is commonly supposed to be happiness. If this is so, instruction of the ignorant in the principles of health must be a matter of the first importance. Plainly, the whole community cannot be put through a medical course. When appropriate subjects have been chosen, a way must be found to introduce the health pabulum into the minds of the people, and in dealing with vast communities the only method is by means of what is called propaganda. How this should be carried out, and the value of health propaganda of various kinds, was the subject under discussion in the Section of Medical Sociology at the recent Annual Meeting of the British Medical Association in Manchester. If no very startling conclusion was arrived at in the discussion, nevertheless its value was great in calling attention to some of the pitfalls in health propaganda, and in enabling enthusiasts in the pursuit of health for the community to compare views with one another.

The Section was largely attended, and interest was maintained throughout its session by a number of valuable contributions to the discussion from very varied aspects. The opening papers, of which the full text is published in our present issue, approached the subject from the points of view of the administrative medical officer, the general practitioner, and the press; and speeches from even more special aspects were not lacking—as, for example, that of the rural sanitarian, who declared that true health propaganda had not yet begun to reach even medical officers of health. It is perhaps not surprising in these circumstances that the final impression is one of fruitful hints being given and taken, rather than of definite conclusions being formulated. Nevertheless, it is not unprofitable or without significance to discover a general (but not unanimous) agreement that "baby shows" are useless or even harmful; that "health weeks" are of little use except as an initial shock in communities where but small attention is given to health matters at all; and that formal lectures to large audiences, as distinguished from more familiar talks to smaller companies, are of very limited value. It was a wise suggestion of one speaker that education in health should not be given as a solid indigestible meal. Posters and leaflets met with considerable condemnation from another speaker, who was emphatic in stating that these productions are not edited with sufficient care, and that highly unsuitable pictures are often introduced to the notice of children and young people. He admitted, however, that it is very difficult to harm the young by propaganda, since they care for none of these things. This is a point too often overlooked by many earnest reformers. On the other hand, it is possible that lurid pictures may leave a permanent mark, quite different from that desired, upon the minds of highly imaginative, ill-balanced, or over-sensitive children.

A number of misunderstandings came to the surface in the course of the debate, and we hope that some of them were removed. They are not new; but seem peculiarly ineradicable from the lay mind. The constant confusion between the General Medical Council and the British Medical Association was still in evidence, and the range and meaning of the former's notices with regard to advertisement in the newspapers and elsewhere had not been clearly grasped. There is no ban on a legitimate publicity; and this still may cover a very wide field. The medical profession and the lay press may alike be reminded that the British Medical Association issued in 1925 a memorandum on indirect methods of advertising, approved by the Representative Body in that year. The most important paragraphs of that memorandum were reprinted in the *Supplement* to our issue of September 11th, 1926 (p. 141), and were circulated to the lay press. Republication of this memorandum, or of those paragraphs, might be of value at the present time, and a few sentences may be quoted here. It may be premised that it is the seeking of personal professional advantage from publicity that constitutes the gravamen of an offence. "It is the recognized duty and right of a medical man to take his share as a citizen in public life, but there is no reason why this should involve any advertisement of himself as a doctor." Publication and lecturing "on semi-medical topics which are of general public interest and require medical knowledge for their proper presentation have been recognized as legitimate, subject to the avoidance of methods which tend to personal professional advantage of their authors. There are many things innocent in themselves which may, by the manner and frequency of their doing, gravely contravene the principle that medical practitioners should not advertise." A practitioner contributing to discussions in lay papers "ought to make it a condition of publication that laudatory editorial comments or headlines . . . shall not be permitted, that his address or photograph shall not be published, and that there shall be no unnecessary display of his medical qualifications or appointments." It can scarcely be maintained that by these requirements the essential needs or purposes of the press and public are in any way cramped or unduly restricted. Full scope for journalistic zeal in the interests of individual and public health is still left.

Another misunderstanding of even greater fundamental importance was disclosed. It relates to the position of the private medical practitioner, whether general or special, in regard to health education and propaganda. It was specifically stated by one lay speaker, whose influence is considerable, that the general practitioner was necessarily so engrossed in the treatment of sickness that he could, and should, take no part in the direction or education of the healthy. This conception of the position and work of the private practitioner is, of course, wholly wrong; and it is exactly from such an idea of the divorcement of curative from preventive medicine that the greatest public danger at the moment arises. The public health or school medical officer and the private practitioner are alike concerned with both. The general practitioner especially, and to an ever-increasing degree, going into the homes of the people, and seeing all classes under all conditions, is actually in his daily practice one of the most potent agents for health instruction, and his advice is now commonly sought in this capacity. The need of the moment is the development of this work in closer connexion with the public health service, whether at clinics or otherwise.

It may be said, indeed, as the outcome of the debate in the Section of Medical Sociology at Manchester,

that the three most valuable means of health propaganda are recognized to be the public health and school medical service, the general practitioner, and the school teacher; that it is not any special or extraordinary effort through these means that is most valuable, but rather their steady daily routine effect; and that since all three should and must be used, severally and in conjunction one with another, there should be no occasion for rivalry or useless comparison between them.

STUDIES ON TUBERCULOUS INFECTION.

As stone by stone the mason builds the temple the idle onlooker, in his thoughtlessness, may pity him for the monotony of his task. Each stone differs but little from its neighbour; laboriously fashioned, it is laboriously lifted, and meticulously placed. The work is slow; culmination is immeasurably far ahead. The onlooker lacks knowledge and vision: the master mason has no such lack. To him each stone is a thing of beauty and of value; each has its appropriate function to the final structure that he can envisage. Full well he knows and appreciates that in other parts of the vast building other craftsmen are busy, each labouring faithfully for the great architect in whom they have implicit trust that he will, at his appointed time, correlate their labours and cause them to fructify.

Recently a series of studies on tuberculous infection have been assembled in a beautiful volume[1] dedicated to the memory of Kenneth Dows, a man of inquiring mind, who, before his untimely death in 1919, established a tuberculosis research fund at Johns Hopkins University. Its authors, Dr. Allen K. Krause, Dr. William Snow Miller, and Dr. Henry Stuart Willis, show us a section of the great temple of the knowledge of tuberculosis. It has its ragged ends ready for additional building, but it is finely conceived and complete enough to stand and be admired alone. For many years these men have laboured at the task of answering two fundamental questions: (1) Does the lymphatic system play a decisive part in the focalization of tuberculous infection; and, if so, what are its significant elements? (2) How does tuberculo-immunity arrive at its effects—that is, less and more chronic disease; and through what agencies does it work? Here at length is their answer. Most students of tuberculosis will have seen and admired the "stones"—articles published sporadically in the *American Review of Tuberculosis* between the years 1919 and 1926. In this volume they have been brought together, and their collective value and the beauty of their structure are shown us in the summary, analysis, and application by Dr. Krause in study No. 15. Criticism and eulogy are alike unnecessary. The work is a marvel of perseverance and direct simplicity. Intelligent and searching criticism of the technical methods and of the conclusions is permissible, as for any work. But, as he reads, the student can feel that this criticism would be welcomed and appreciated by these authors; such is the open-minded and humble spirit in which they have approached their task.

Standing by itself the structure is worthy, but a wider view of contemporary work confirms its value. Krause, Miller, and Willis have approached their problem from the laboratory standpoint, using mainly the guinea-pig and the rabbit as keys to the solution. The application to human disease, caused by natural infection, of conclusions derived from a study of the artificially produced disease in animals may be a source of dangerous error. But other craftsmen are at work. Their countryman Opie and his collaborators are seeking the solution of much the same essential problem by another route—namely, that of clinical investigation. Their work has not yet been collected, but those who are familiar with it will realize how well it dovetails with these studies, and how the two strengthen and bear witness to each other's conclusions.

The temple of knowledge knows no bounds of land or race, and the published researches of Calmette in France, using bacteriological, post-mortem, and clinical material as a medium, will further underline the truth and enlarge the scope of what we read in this memorial volume. Master craftsmen all. But what of the onlooker, in this case neither idle nor ignorant, Kenneth Dows? In their introduction the authors pay tribute to the "simplicity and directness" of his character. Though no craftsman by training, the clearness of his vision showed him the simple but basic problems needing solution. His public spirit made the work possible. It would seem that by the simplicity and directness with which they have handled their task these men have paid him the highest tribute and built a memorial in which he would have taken pride.

[1] *Studies on Tuberculous Infection.* By Allen K. Krause, William Snow Miller, and Henry Stuart Willis. Baltimore: Assembled from reprints of papers published in the *American Review of Tuberculosis*, 1919-1926. 1929. (Sup. Roy. 8vo, pp. xiii + 591. Illustrated.)

NOISE.

THE problem of the prevention of unnecessary noise is a difficult one. The deputation from the British Medical Association which waited on the late Minister of Health on December 4th, 1928, got little out of Mr. Neville Chamberlain beyond an expression of sympathy, accompanied by some questions to which it is not easy to find definite answers. He wanted proofs of the injurious effects of noise in concrete cases, and asked for statistics, which, unfortunately, are not forthcoming. At the Annual Representative Meeting at Manchester the West Suffolk Branch, represented by Dr. Grace Griffith, moved to instruct the Council to take further steps, but the Council, after its experience with the late Minister of Health, did not see its way to further action at present, and the meeting decided to pass to the next business. The mischief of noise in modern life, especially in town-life, is notorious and admitted by all; but the concrete evidence demanded by Mr. Chamberlain is extremely hard to come by. It cannot be shown on the stage of a microscope or in a jar of spirit, nor can the effects of noise on the nervous system be satisfactorily separated from the many other noxious results of modern life. The police cannot lay hands upon a noise, however tremendous it be, so as to bring it before a magistrate for condemnation, until they are equipped with standardized recording instruments. Indeed, the question of definition of noxious noises and the distinction of harmful from harmless sounds is one of the fundamental difficulties of the whole matter. Many townspeople fondly believe that quiet and peace are inherent in agricultural surroundings, but we learn from Dr. Grace Griffith that a mechanical pig-feeder may disturb the calm of the fields and shatter the nerves of a susceptible patient. Despite all these difficulties, Dr. T. G. Nasmyth and his fellow members of the Edinburgh and Leith Division of the Association have not let the question sleep, but have agitated to such good effect that clauses making noise legally a nuisance, suggested by them, have found a place in a bill which

the Edinburgh Corporation is promoting in Parliament. The clauses referred to are the following:

"33. Any trade, business, or occupation carried on within the city in such a way as to cause unreasonable or unnecessary noise or noise which is capable of being prevented or mitigated and which is dangerous or injurious to health, shall be deemed to be a nuisance within the meaning of the Public Health Acts.

"34. (1) The corporation may from time to time make by-laws for the following purposes, or any of them, namely:

(*a*) For the prevention, removal, or mitigation of noise affecting injuriously, or calculated to affect injuriously, the health of the inhabitants of dwelling-houses or occupied apartments;

(*b*) For the prevention, removal, or mitigation of any nuisance or annoyance due to unreasonable or unnecessary noise or noise calculated to be dangerous or injurious to health; and

(*c*) For the reduction of preventable noise.

"(2) The provisions of Section 207 (provisions in regard to by-laws) of the Streets, Buildings, and Sewers Order of 1926 shall apply to all by-laws made under the provisions of this section."

It will be seen that these clauses do not specifically refer to traffic noises, and it seems doubtful whether such noises could be attacked as nuisances. It was probably for some such reason that Mr. Chamberlain suggested that the Minister of Transport was a fitter person than himself to deal with vehicular noise. Whatever the limitations of scope of the proposed clauses, we wish the Edinburgh Corporation success in pushing its bill through Parliament, and we heartily congratulate our Edinburgh colleagues on their public-spirited pioneer effort. It will be recalled that the Ministry of Transport took up the question and held a conference on the subject of traffic noises and priority of traffic at cross-roads, of which the report and proposed regulations were published on May 10th, and commented upon in our columns on June 22nd. The new Motor Cars (Excessive Noise) Regulations came into operation last week, and it is to be hoped that they will be duly enforced and will mitigate to some extent the noise nuisance, but there are considerable difficulties to be foreseen as long as "excessive noise" is not clearly defined. We may hope also that the circular issued on August 2nd by the Minister of Transport, appealing to motorists to refrain from using "exceptionally strident and disturbing" motor horns, will do something to abate the pandemonium of the roads.

SCIENCE AND EMPIRE MARKETING.

THE third annual report of the Empire Marketing Board, which reviews the twelve months ending May, 1929, was published by the Stationery Office on July 23rd, and deals with the three branches of its work—scientific research, economic investigation, and publicity. In no other department of the national life can the increasing importance of science be more clearly seen. The Board has taken many opportunities of financing scientific research, and a most informative section of the report is Appendix II, which contains details of the purposes for which grants have been made. The first two pages of the appendix cover a wide field, including grants to the University of Cambridge for biological and agricultural research, to the Imperial College of Tropical Agriculture in Trinidad, to the Amani Institute in Tanganyika (the research station established by the former German Government), and to a research station in tropical Australia. The grants are spread impartially over the Empire, and those who realize how research stations are the power houses of science will find even the bare record most stimulating. Co-ordinated and directed research is being applied to all the problems which come within the scope of the Board's activities over the world-wide field of Empire organization in a way to which the past supplies no parallel. Much attention has been given lately to research on the mineral content of pastures, with special reference to certain deficiencies in the soil and their effect on the growth and strength of live stock; results of great practical value have been obtained already in Scotland and in New Zealand. But the research is more widespread than that, and takes in the Rowett Research Institute at Aberdeen, the Australian Council for Scientific and Industrial Research, the New Zealand Government, the Government of Southern Rhodesia, the Falkland Islands, and Palestine. It is already obvious that these researches will have a great interest for all students of human nutrition; they link up with recent work on the influence of foodstuffs on the human body and resistance to disease. Investigations of metazoan immunity with reference to animal health are being continued at the Liverpool School of Tropical Medicine; tsetse-fly research is being conducted by the Government of Tanganyika, and entomological studies proceed in Great Britain, New Zealand, and Australia. Many of these lines of research are dealt with in special publications of the Board, and the only serious criticism we have to make of this annual report is that in dealing with many matters of great scientific interest in new fields it is almost too condensed in its statements. The excellent advertising of the Board with regard to Empire products has contributed to a great increase in their use, and it is at least worth while considering whether the "Romance of Empire science" is not as worth while advertising as the slogan "Eat more fruit." Since this report was in type a General Election has taken place and a Labour Government is now in power; it is already certain that colonial development is to have special attention, and it has become an accepted axiom that colonial development depends more on the scientific conquest of environment than on any mere expenditure of money. Furthermore, the new Government has already stated that it intends to maintain the Empire Marketing Board, which has the spending of the annual grant of £1,000,000. In comparison with the expenditure represented by the united budgets of Great Britain, the Dominions, India, and the Colonies, the sum of £1,000,000 is very small, and out of this only a fraction is spent on scientific research. But the existence of the Board enables what are in fact world economic scientific problems to be surveyed as a whole. The necessary research is then directed to making good the gaps in our knowledge, and the work required is carried out in whatever is the most suitable part of the world. In one aspect of its work the Board looks upon the Empire as an experimental laboratory, and it has at its disposal all climates and conditions. When we add to this that it has associated with its work some of the most eminent scientists of the day, we realize that science is more and more taking its true place as one of the main directing considerations in the framing of policy for the British Commonwealth of Nations, and because of the world-wide spread of this Commonwealth the solution by us of scientific problems benefits the whole of civilization.

"A TRIUMPH OF PREVENTIVE MEDICINE."

TO many of the public, as well as to many sanitarians, preventive medicine in the tropics spells Panama. In a sense this is right and proper, for the magnitude of the task undertaken by the Americans was matched by the thoroughness of their methods and the success which crowned their efforts. It is well, however, to remember that the work in Panama cannot be taken as a measure of what it is practicable to achieve elsewhere. The success gained by Gorgas and his successors, following the application of newly acquired knowledge, stands out in such dramatic contrast to the tragic experience of the French canal company, that admiration for the results has sometimes been blind to important circumstances without which the great work could never have been done. British colonial legislators have been known to reproach their

health officials for their failure to go and do likewise. Such should note the words of Colonel Chamberlain, the present chief health officer of the canal: "Endowed by treaty with absolute sanitary jurisdiction over a wide area, and provided with almost unlimited funds, the authorities from the United States in 1904 were in a position to cope effectively with the health situation on the Isthmus, a *situation which had theretofore defied control.*"[1] It should be recalled, too, that the area dealt with is a very small one compared with many of the tropical territories where mosquito-borne disease is still uncontrolled; that more than half of the present annual budget of one and a half million dollars for the health department comes from that department's earnings, and the remainder from appropriations by Congress, so that the cost of present maintenance does not, any more than did that of the original works, form a charge upon the inhabitants of the area. The cost of "strictly antimosquito work" (exclusive of screening) for the last ten years has averaged about 100,000 dollars per annum, while a further 50,000 dollars is spent on the same work from military funds. The entire population benefiting from this expenditure is about 130,000. The work has now reached a point where the principal problems of the public health are no longer distinctively tropical. It may be doubted, however, whether Colonel Chamberlain is justified in interpreting the results as "one of the strongest links in the growing chain of evidence which supports the recently evolved theorem that the white man can prosper in the tropics." The recently evolved theorem would have us believe that the white man can populate the tropics permanently and healthfully, and without the aid of coloured labour. To establish this will require evidence of a different sort from the striking demonstration of disease control which the Panama sanitarians have furnished. The three anopheles noted by Chamberlain as important malaria carriers are *albimanus, tarsimaculatus,* and *bachmanni,* with *eransi* as a probable carrier. One of the puzzling problems of malaria appears in the apparent innocence of *Anopheles argyrotarsis* in Panama while it is an important carrier elsewhere. The gradual progress of the Panama work from the pioneer, almost makeshift, methods of early days to the permanent measures now being extended over wider and wider areas makes fascinating reading and commands the admiration of the world.

THE LAW AND MEDICAL PRACTICE.

MEDICAL practitioners, dentists, and veterinary surgeons alike, to say nothing of the lawyers, will be grateful to Dr. Fred Bullock for his essay entitled *The Law Relating to Medical, Dental, and Veterinary Practice.*[2] It will be found to be meticulous in its accuracy, explicit in its references, and, unlike most such books, really interesting in its arrangement and exposition. The chapters which enunciate and explain the present state of the law relating to professional discipline, unqualified practice, the recovery of fees, and negligence, in so far as these concern medical, dental, and veterinary practice, are led up to by a brief but sufficient historical sketch explaining the origin and the development of the law in question, and showing the struggles of the apothecaries, the surgeons, and the physicians to differentiate themselves from the unqualified practitioners, and their feuds with each other. This part of the volume is not only of much interest in itself, but is essential to the proper understanding of the present state of affairs—to an appreciation of the limitations of the Acts under which the professions are carrying on their work and of many of the difficult problems which still confront them. Towards the end of the volume the questions of medical secrecy and of lunacy certification are dealt with, and some notable and valuable suggestions are made for the practical solution of some of the important points involved. In these and similar matters the author seems *fully to appreciate the position of the professions.* For instance, "That the prohibition of advertising is desirable cannot be gainsaid, for it is clearly in the public interest that the doctor shall be allowed to have not that reputation which can be made by self-advertisement, but that alone which comes from the care and skill he shows in the exercise of his art. . . . The sale of secret remedies can flourish only on the view that every member of the public is competent to diagnose his own complaint and to select an appropriate remedy, and no trained practitioner should subscribe to such an erroneous assumption. . . . Though advertising is a virtue in commerce, it is a vice in a professional man." The essential difference between the employment or covering of unqualified assistants or persons *and the employment of expert lay assistance to carry out* special treatment under the direction of a qualified practitioner is noted; and even the recent arrangement of the Society of Apothecaries, at the instance of the British Medical Association, for the examination and registration of such assistants in the sphere of electro-therapeutics is described. Here and there in the volume there appears a sort of wonder that, in spite of the absence of professional demand, public opinion has not insisted upon the prohibition of unqualified practice. Of course, this is forbidden in the field of dentistry, and the author points out the less fully appreciated fact that the same is true of the treatment of venereal disease. "Since persons lacking a medical education cannot possibly acquire the essential knowledge and skill by any means other than experiment, with its concomitants of unnecessary suffering and danger to the patient, we might well ask why the law continues to allow them to practise. If unqualified practice in medicine were prohibited the hardship inflicted on any class of persons would certainly be a lesser evil than the continuance of the present dangerous laxity. Can there be any reason in the public interest why unqualified persons should be allowed to treat diseases such as cancer, consumption, epilepsy, locomotor ataxy, paralysis? Is cancer more easily curable than venereal disease? Is paralysis less important than an aching tooth? It is clear, at all events, that the present state of the law cannot be regarded as final." After a different fashion, and with a different purpose from that of Dr. Bullock, Lord Riddell discusses certain *Medico-Legal Problems*[3] in four papers he has read before the Medico-Legal Society. They are concerned with "The surgeon's responsibility," "Abortion," Medical confidences," and "The sterilization of the unfit." In this small book we have the views of one who formerly practised as a solicitor, and who in many ways has shown himself interested in the work and the well-being of our profession, and anxious in a very practical fashion to further its efforts for the public good. Here and there, especially in the last essay, the doctor with specialist knowledge will note the failure of the non-expert to appreciate fully some vital factors, but throughout there is a clear posing of the problems to be considered, together with a shrewdness of opinion and of judgement, which are valuable contributions towards their solution. An addendum to the paper on "Medical confidences," referring to the Public Health V.D. Regulations, contains the following sentence: "If the regulations were *intra vires* it might well be contended that statutory secrecy had been established." It is curious, therefore, that there should be no

reference to the very important anonymous case (duly recorded in Dr. Bullock's book) in which, in July, 1927, Mr. Justice McCardie said: "Doctors are not in a privileged position because they are acting in a department under control of the Minister of Health through the local health committees. Nothing in the regulations saves a doctor from disclosing, if ordered by the Court, all the information he might have of the facts he has gained while acting under the regulations." While we are unable to endorse fully the claims made for sterilization in Lord Riddell's last chapter, the plea, as he states it, may well be regarded as a reinforcement of the suggestion now being made for an inquiry by Royal Commission, or some similar method, into the whole subject of the causation and prevention of mental deficiency.

"THE HOWARD JOURNAL."

THE official organ of the Howard League for Penal Reform is *The Howard Journal*, which is described as a review of modern methods for the prevention and treatment of crime and juvenile delinquency, and is said to be the only periodical publication devoted to the scientific treatment of crime. It is published half-yearly, and the current number, dated June, 1929, should be both interesting and valuable to the increasing number of persons who are concerned with the sphere of social effort indicated—magistrates, prison officials, medical men and women, psychologists and teachers, and other social workers. It is of some interest to note that among the contributors are Dr. R. G. Gordon and Mr. Charles Duff, whose remarkable little books—*Autolycus, or the Future of Miscreant Youth* by the former, and *A Handbook of Hanging* by the latter—were recently reviewed in these columns. Other items include a particularly informative series of reviews, an account of current and recent activities of the Howard League both at home and in the Colonies, and comments on such documents as the reports of the Prison Commissioners, of the Children's Branch of the Home Office, of the Street Offences Committee, and of the Royal Commission on Police Powers and Procedure. There is an account of the Federal Industrial Institution established by an Act of Congress in 1924 at Alderson, West Virginia, which, with its accompanying illustrations, seems almost to indicate that it is highly desirable for many persons to qualify to become inmates. It has a capacity for 500 women over 18 years of age whose "offences thus far have been mainly violations of the Harrison Narcotic Act, the Prohibition Act, the Postal Act, as well as all kinds of crimes in the district of Columbia." It would have been interesting for English readers to have had a more exact indication of the status of this institution and the field which it is intended to cover. Perhaps the two most important articles, however, are one which describes the activities of "The psychological clinic," by Dr. Cyril Burt, and one by Dr. J. Hall Morton, the governor and medical officer of Holloway prison, entitled "Alcoholics in prison." The former of these articles is timely in view of the establishment of a child guidance clinic in Islington under the auspices of the Child Guidance Council and the London County Council, with the approval of the Board of Education. To see clinics of this character in full working order we must go to America, where for more than ten years they have been developing under a great variety of circumstances, and doing valuable experimental work by means of the Commonwealth Fund, established in 1918 "for the welfare of mankind" by Mrs. Stephen V. Harkness. This fund has lately provided the necessary financial support for an extension of the movement in this country, and for the establishment of the clinic just mentioned. Dr. Cyril Burt's article affords a clear indication of the methods and objects of such a clinic, as also does a small pamphlet just issued by the Child Guidance Council from 24, Buckingham Palace Road, S.W.1. Dr. Morton's article is illuminating on certain aspects of alcoholism in women, and may well lead to further and better directed efforts for its prevention and control.

SANATORIUM TREATMENT IN SWITZERLAND.

THE Queen Alexandra Sanatorium Fund owes its origin to the late Lord Balfour of Burleigh, by whose exertions the Queen Alexandra Sanatorium was built at Davos for British consumptive patients of small means some years before the war. Subsequently the great increase in costs of all kinds made it impossible to reopen the sanatorium at at a fee within the reach of the class of patient for whom it had been intended, and the council was faced with the alternatives either of altering the whole character of the institution, or of selling the building and devoting the proceeds to helping patients of small means to get treatment in an Alpine climate in some other manner. It decided on the latter course, and details of the new arrangement were published in the *British Medical Journal* (1922, vol. ii, p. 698, and 1924, vol. ii, p. 480). For several years the income of the fund has been devoted to making grants to selected cases staying at Davos during the winter months. The cases to be helped are chosen on the results of medical examination by honorary examining physicians to the fund at various centres throughout Great Britain, and of inquiry into their means. The grants are made for about six months, at the rate of £2 a week, and are conditional on the assisted patient staying at an approved sanatorium or pension at Davos; unless there is a resident medical practitioner at the sanatorium the patient must place himself under the care of one of the visiting physicians to the fund at Davos. In the annual report of the fund for 1928–29 it is stated that last winter fifty-three patients were helped. The average cost per week of a careful patient in the cheaper establishments at Davos is estimated to be not less than £5 per week, which means that in addition to the grant from the fund the patient will have to spend about £3 a week. The ordinary income of the fund is about £2,000 a year, and has recently been augmented by the amalgamation with it of the St. Moritz Aid Fund, a similar though smaller organization formerly operating at St. Moritz. Application forms are issued on request by the local secretary, Mr. W. G. Lockett, The British Consulate, Davos Platz, Switzerland, in September. Advanced cases are not eligible.

KING FUAD AT THE ROYAL COLLEGE OF SURGEONS.

THE King of Egypt paid a visit, on August 1st, to the Royal College of Surgeons of England, and was made an Honorary Fellow of the College. Lord Moynihan, the President, on presenting the diploma to King Fuad, referred to the close connexion of the Royal College of Surgeons with the Egyptian School of Medicine. Fellows and members of the College had been teachers in the School, and until recently the post of dean had been held by an English Fellow of the College. Dr. Aly Ibrahim, the present dean, had recently been made an Honorary Fellow, and within recent years nine Egyptians, trained in the School at Cairo, had become F.R.C.S.Eng. by examination. The President also referred to the great personal interest His Majesty took in the faculty of medicine at Cairo and the Kasr-el-Aini Hospital, for the new building of which he lately laid the foundation stone. King Fuad, having signed the Roll of Honorary Fellows, inspected the museum and other parts of the building.

THE Royal College of Physicians of London will be closed for the summer vacation from August 12th to September 14th, both days inclusive.

THE HEALTH OF LONDON.

REPORT FOR 1928.

THE report of the county medical officer of health and school medical officer, Dr. F. N. Kay Menzies, records the progress of public health in London during 1928.

Births and Deaths.

The population of the County of London in the middle of 1928 is estimated at 4,469,000 (including 10,800 non-civilians), a decrease of about 80,000 since last year. The births were 72,352, equivalent to a birth rate of 16.2 per 1,000, as against 16.1 in 1927; in the last quarter of 1928 the births fell below the lowest number recorded for this quarter in 1918, when the effects of the war were at its maximum. The deaths were 53,695, giving a death rate of 12.1 per 1,000, the same as that of 1927. Measles was epidemic in the year, causing 1,358 deaths, as against 181 in the preceding year; the weather conditions were not so favourable to infant life as in 1927, and the deaths under 1 year per 1,000 births increased to 67, as against 59 in the preceding year; this latter rate, however, was the lowest recorded in London.

Small-pox.

A fascinating and illuminating account is given of the origin and travel of small-pox in London and the Home Counties. *Small-pox was brought to the South of England in December, 1927, by a man who had tramped from Lincolnshire to the East Preston casual ward, near Worthing.* The nature of his illness was not recognized until secondary cases occurred a fortnight later; by this time large numbers of vagrants in the casual ward had been infected, had left the institution, and were scattering the disease over the adjoining counties. During January, 1928, cases were reported in the casual wards at Guildford, Isleworth, Barnet, Edmonton, and Ware. The source of infection of the first two cases in London could not be traced; the third case was infected in the Southwark Hospital by a vagrant admitted from a Salvation Army shelter, who was first thought to be suffering from influenza and then from chicken-pox. Eight direct contacts acquired the disease, and one of these, a cleaner in the hospital, gave rise to four other cases in her family. In February a man was found in the initial stage of small-pox in the Metropolitan Asylums Board Hostel in Holborn: no spread developed from this source. The infection was traced to the Holborn and Finsbury Hospital, Islington; prompt and vigorous measures reduced the outbreak to five cases. In March a visitor from Middlesex probably introduced the infection into the Springfield Mental Hospital in Wandsworth: 12 cases occurred, including that of a female nurse. The disease spread to the general population of the borough and, lasting till July, caused 76 other cases. No original source of infection was discovered for cases appearing in Poplar in April, or for the 9 cases in Lambeth Hospital in April and May, nor for the 29 cases arising in the St. Marylebone workhouse in June. Associated with the outbreak in Wandsworth were a few cases in South Lambeth in June and July, but the main outbreak in Lambeth was traced to a schoolgirl who visited her mother, an in-patient at St. Thomas's Hospital. As the result of these visits there was a series of "missed" cases in the neighbourhood of the hospital, and in September the infection was taken to the hopfields by one of these. On their return to London hop-pickers who had been infected spread the disease in Poplar and North Lambeth. Poplar had 68 cases in all in the year and Lambeth 53; cases in other boroughs brought the total for London up to 285. In October the outbreak, still present in West Ham, was started by the occurrence of an unrecognized attack in the proprietress of a dressmaker's establishment; up to May, 1929, some 500 cases have been reported. This outbreak on the eastern border of London constitutes a menace to the county, as many of the patients and their contacts are employed in or visit London daily. (The last available return shows that small-pox is present in Bethnal Green, Islington, Poplar, St. Pancras, and Stepney.)

How long it will take to clear small-pox out of London is a matter for conjecture, and depends largely on the response to appeals to the unprotected to be vaccinated.

Diphtheria.

The notified cases of diphtheria numbered 12,155; death occurred in 399, the case mortality being 3.3 per cent. In spite of improved sanitary conditions, better housing, more efficient medical supervision of children in the school and home, earlier diagnosis, earlier treatment and admission of cases to hospital, diphtheria in London has shown no diminution in incidence and mortality during the past few years. The average number of cases yearly between 1903 and 1919 was about 7,850, and the number of deaths 633; in the period 1920-28 the average number of cases was 12,960 and of deaths 703. There has been a tendency for the disease to become established in certain localities in London, and for it to develop exacerbations of virulence from time to time. The increasing number of children actively immunized against diphtheria is all to the good, but the present amount of dilution of the total child population by so small a number can exert but little effect upon the incidence of diphtheria as a whole; every effort must be made to prevent the transfer of infection from patients and "carriers" to the uninfected. Many carriers soon cease to harbour the bacilli, but others remain capable of spreading infection for long periods; for this some abnormality of the nose or throat is responsible. Arrangements have been made for dealing with such children at the special clinics at Guy's, London, and St. Mary's Hospitals. As a routine the children are given a polyvalent vaccine composed of twelve virulent strains of diphtheria bacilli isolated from carriers; usually four injections are given, at weekly intervals, of doses containing 5, 10, 15, and 20 million dead bacilli. When the condition has been found to be due to the presence of bacilli deep down at the base of the tonsillar crypts, tonsillectomy and the removal of adenoids, if present, have been found sufficient to remove the infection. The condition more frequently found—namely, that of children harbouring the bacilli either in the nose alone or in the nose and the throat or the ear—is more difficult to treat. With the use of nasal douches, and the satisfactory remedying when possible of any nasal abnormality present, the bacilli disappear, not only from the nose, but from other parts which have been infected from this source.

The Control of Measles.

The deaths from measles totalled 1,358, the highest number since 1922. All measures hitherto tried for the prevention of measles have proved valueless; in practice, school or class closure is not resorted to until the outbreak has become well established, and by that time all the susceptibles have already been exposed to infection. There has always been difficulty in obtaining sufficiently early knowledge of the first cases; the policy of excluding unprotected children from class-rooms for selected periods on receiving information of the first cases of measles has proved as ineffective as school or class closure. Owing to the fact that the first case in a family may be in a child not yet in attendance at school, exchange of information with the medical officers of health of the metropolitan boroughs was arranged in 1921. During the past three epidemics efforts have been concentrated upon the schools situated in overcrowded and insanitary areas; the school nurses visit daily to find cases and report any suspicious absentees, who are followed up by the school attendance staff. Any cases of measles thus disclosed are reported to the borough medical officer of health. In Wandsworth time was saved by the school nurses passing on the information direct to the health visitors, who visited the suspicious absentees; the number of deaths from measles was less than during previous epidemics. In addition, when measles breaks out in a school, leaflets are distributed by the borough medical officers through the school organization, advising the parents if their children suffer from a "cold" to isolate them and seek medical advice.

Tuberculosis.

The artificial light treatment made available was very little used by the tuberculosis officers; where used no evidence was forthcoming of benefit derived by the patients from this form of treatment. Dr. Menzies considers that the best results are only obtained when light treatment is given as an additional method of treatment, under suitable conditions, in residential institutions in the country, where all methods of treatment are available, in addition to fresh air, good food, and a regular regime.

There is much evidence that the help and advice given at the right moment by the Tuberculosis Care Committee enables the patients to re-establish themselves in life after residential treatment. Handicraft classes for dispensary patients unfit for ordinary employment have proved of considerable value: they have improved the morale of the patients long unaccustomed to work; the rekindling of the work habit has ultimately led to the patients' obtaining permanent employment. Incidentally, the patients appreciate the opportunity of obtaining pocket-money by the sale of the articles made.

The Metropolitan Asylums Board has adopted a scheme which provides for the training of selected patients; nine posts for nurses and nine for domestic servants are to be reserved for satisfactory trainees. The Invalid Children's Aid Association has co-operated in the scheme for boarding-out children living in contact with cases of advanced pulmonary tuberculosis; in a few cases also, where it was not possible to make other arrangements, children have been provided for in order to enable their mothers to accept institutional treatment. During the year 149 children were dealt with in this way.

Venereal Disease.

The number of new patients with venereal disease dealt with by the hospitals under the London and Home Counties scheme during 1928 was 16,401, of whom 5,270 were suffering with syphilis, 10,896 with gonorrhoea, and 235 with soft chancre. Dr. Menzies reports that the need for improving conditions likely to cause patients to discontinue attendance at venereal disease clinics continues to receive careful attention. A very large number of non-venereal patients presented themselves for examination, indicating that the public are becoming more and more aware of the serious nature and grave after-effects of the venereal diseases. There is a gradual advance in the number of attendances made by the new V.D. cases—46 in 1928, as compared with 40 in 1927, and 38 in 1926. The number of pathological examinations made for private practitioners is increasing; 459 medical practitioners are now entitled to free supplies of the approved arsenobenzol preparations for the treatment of their private patients.

Experience has shown the value of the provision of accommodation in hostels where young women and children under treatment could be lodged during the period of infectivity; 235 patients were dealt with in this way. In order to maintain treatment and observation, in 1928 arrangements were made for transfer of such patients, when no longer infectious, to certain rescue homes providing vocational training in domestic and other work.

Milk.

The biological examinations which could be completed showed that of 1,605 samples of milk, 143, or 8.9 per cent., contained tubercle bacilli; in 1927 the corresponding figure was 7.8 per cent. Much of the milk sent to London is bulked at the depot in the country before dispatch; this mixing of the milk has always made the tracing of tuberculous milk to its source difficult, and the position has become even more difficult since the recently introduced use of glass-lined containers, which may hold as much as 3,000 gallons, derived from a few 200 farms. Obviously the introduction of a single infected milk into the tank may infect the whole of the milk in the tank—whether the dilution of the tubercle bacilli so brought about is a compensating advantage or not cannot at present be decided. A large number (397) of the guinea-pigs injected with the milk died of an acute intercurrent infection by some organism other than tubercle. In the past year increased evidence has been obtained as to the frequent association of the death of the guinea-pig with unhygienic conditions at the farm; consequently the practice has been continued of informing the county medical officers of health concerned of such occurrences. On examination, milk produced in London was found to provide slightly less (0.9 per cent.) tuberculous samples than imported milk; there was, however, a marked difference (11.4 per cent.) in the percentage of guinea-pigs succumbing to an acute intercurrent infection; the many opportunities of contamination during transport, in wholesale and retail storage, and in final distribution, is undoubtedly a factor adverse to the cleanliness of milk of distant origin.

Rheumatism in Children.

The preponderance of rheumatic infection in producing chronic invalidity becomes more marked each year; heart disease, rheumatism, and chorea accounted for 31 per cent. of the children who had been three months out of school on account of illness. In addition to the rheumatic supervisory centres at voluntary hospitals, two directly administrative supervisory centres have been established in Wandsworth, and there has been a further extension of beds placed at the council's disposal for rheumatic children by the Metropolitan Asylums Board. The nominations for these beds, however, are far in excess of the accommodation, and those not so provided for are referred to the Invalid Children's Aid Association, who report on the children and arrange for the treatment of many of them. The supervisory centres are especially useful in supplementing the routine examination of the children in schools: they afford an opportunity for a more extended examination and review of the indefinite symptoms and signs that are the features of early rheumatism, and avoid the harm done by labelling merely delicate children as rheumatic. They also serve as a "clearing house" for shepherding the rheumatic child into the channels that fit his particular condition. Of 305 homes visited in connexion with the Great Ormond Street clinic, 111 were reported damp and 81 as ill-lighted.

Maternal Mortality.

The report includes a discussion of the fertility of married women in connexion with the maternal mortality rate; evidence is produced that deaths from accidents of childbirth in London tend to increase as the birth rate falls. The mortality from puerperal fever has been excluded from consideration in this connexion owing to acceptance of Longstaff's observation (for which further evidence is given) that the mortality from puerperal fever is subject to periodical fluctuations closely related to the mortality from erysipelas and in a less degree from scarlet fever. A comparison of maternal mortality in a group of boroughs consisting mainly of better-to-do residents with a group of poorer boroughs shows that the dominating factor in maternal mortality is not social condition *per se*, but the fertility of the women compared. In 1909 it was shown that where allowance is made for the difference in the ages of the married women the fertility of a group of metropolitan boroughs with a poorer class population is about one and a half times that of a group of the boroughs having the highest proportion of well-to-do residents. Pronounced changes in the fertility rate have masked the effects of the ever-widening scope of administrative effort to improve the conditions of childbirth. From a consideration of the maternal mortality from all causes in England and Wales during the period 1911-21, the conclusion is reached that the maternal risk in childbirth is lowest at the ages under 25 years, and increases rapidly with age after the thirtieth year. At the age period 15-20 there is a high post-natal mortality due to the far greater risk of death from convulsions and puerperal albuminuria at this age, especially in primiparae; the lower death rates from pre-natal and natal causes, however, make the total death rate exactly equal to that of the age period 20-25. London figures relating to the case mortality from puerperal fever according to the age of the mother during 1911-14 show clearly the increase of mortality with age. The same result is reached by a comparison of parity and puerperal fever; other figures given also show a lower case mortality among primiparae. It would seem, therefore, that resistance to the infective process (presumably greater at younger ages) rather than the severity of the confinement is the predominant factor in the occurrence of puerperal fever. The hypothesis that the doctor is a carrier of puerperal infection receives no support: in those metropolitan boroughs where obviously the greater proportion of the births have been delivered by doctors or medical students the puerperal fever mortality is lower than in a group of boroughs where midwives' cases are in a majority. The section relating to maternal mortality, probably the most valuable original contribution to public health contained in the report, should be studied in its entirety.

Flat Feet in School Children.

Special attention has been paid to the condition of the feet of the children by several school doctors, following on the observation by an orthopaedic surgeon of the number of boys attending for treatment at hospital for painful flat-foot within a year after leaving school and going to work.

Some of the children, varying from 3 to 12 per cent. of those specially examined, were found to present various degrees of flattening of the arch of the foot when in repose, but it is pointed out that it is by no means certain that these children will be ones who fail later in industry owing to

the development of acute flat-foot causing pain and disability. The children who present themselves for licensing as stage dancers are found to have feet which in repose are flat, but they are perfectly mobile; the children possess well-developed calf muscles, and on springing into activity the feet become well arched. The worst symptoms of flat-foot occur in the high-arched, thick-set or sturdy foot, which offers painful resistance to distortion of its joints. To anticipate and prevent the development of flat feet in adolescence the physical exercises given in schools must be directed towards increasing foot mobility and muscular development, and should be carried out in flexible shoes or, better still, without any footgear.

Hop-pickers.

A report on the examination of 1,510 children before and after going hopping showed that, in somewhat over half, their health benefited; in about 4 per cent. deterioration of health had occurred. The weather was exceptionally favourable last year; *the short hopping season of fifteen days* was bright and sunny throughout, and the dangers to health were less than usual. Pneumonia was less frequent, and so were burns and scalds owing to the lessened need for fires for drying clothes, and the increased possibility and practice of outdoor cooking. At least forty medical dispensaries and branch dispensaries were available. At the Hop-pickers' Hospital at Marden, among 646 children treated there were 11 cases of conjunctivitis and "hop-eye" and 13 of dermatitis and "hop-rash." "Hop-eye" and "hop-rash" occur chiefly among women and children; they are probably the result of protein sensitiveness. Shortly after the eyes have been rubbed with fingers, dirty from hop-picking, they begin to smart. A conjunctivitis or considerable oedema of the eyelids, with or without conjunctivitis, is seen; the trouble rapidly yields to treatment. In "hop-rash," within a few hours an intensive papular erythema appears, which, if not treated, goes on to pustulation; general constitutional disturbance may occur, the patient complaining chiefly of extreme drowsiness. Thirty cases of enteritis were treated; the cause was either unsuitable food or food actually unfit for consumption, and the disease was sometimes traceable to unripe fruit, especially apples and hedgerow fruit. Some of this illness might be avoided if definite instruction on the subject were given in the schools before hop-picking began. Although improvement has taken place in the hop gardens during recent years, the conditions under which the hoppers live are still often unsatisfactory. Most of the huts have no windows; in some areas there is no supervision as to the numbers sleeping in the huts, and consequent overcrowding. In many instances the latrine accommodation is insufficient and often filthy, causing reluctance to use them and consequent constipation; the water supply is very unequal, many encampments having to rely on streams and ponds, in some cases half a mile away. The dangers of burns and fire are very real. The hutments are often of wood, and the bedding is loose straw on the floor; some of the hop-pickers use oil stoves inside their huts. Three children were burnt to death in a hop-picker's hut owing to the straw being set alight by a naked candle. Reference is made to a conference at the Royal Sanitary Institute in April, 1928, when the county medical officer for Kent, Dr. A. Greenwood, pointed out that there was ample machinery for securing satisfactory conditions, but the rural district councils tended to show leniency in the administration of the by-laws. He suggested compulsory registration of encampments and annual licensing, the licences only to be granted if the provision made before occupation satisfied the district council concerned. In the hopping season probably 100,000 workers migrate into the Kent hop gardens. The bringing together in crowded encampments of families derived from many of the poorer districts of London gives special opportunity for the spread of infectious disease and, as a consequence, the return of the hop-pickers to London is the signal for the outbreak of infection in new centres. In 1928 an outbreak of small-pox among the hop-pickers was followed by the appearance of the disease in London schools hitherto free, the first cases being the children who had been away hopping.

Sanitary Administration.

In other sections of the report are items of much interest. The promotion of legislation prohibiting the use of underground rooms as living rooms is being considered. The council intimated its dissatisfaction to keepers of common lodging houses at the increased number (125) of children found in them on the occasion of the census of homeless persons in February; on an emergency children under 14 might be admitted for one night in the ordinary type of common lodging house; even at houses with approved accommodation for children they should not be kept there for an indefinite period.

Chlorination of the water in the outdoor swimming baths in the council's parks has effected some improvement, but the use of filters improves its appearance and purity.

A survey of the public sanitary conveniences for men and women within the county was made. Although the standard of excellence in sanitary attainment in London has nowhere been surpassed, the influx of women into the metropolis of late years calls for more provision for women. A cleaner and purer lower part of the Thames is foreshadowed; a unit of plant has been installed at the Northern Outfall capable of treating from 5 to 10 millions a day of the effluent from the sedimentation tanks with activated sludge.

Scotland.

Retirement of Sir Donald MacAlister.

THE announcement that Sir Donald MacAlister, Bt., M.D., had decided to retire from the positions of Principal and Vice-Chancellor of Glasgow University was briefly mentioned in the *British Medical Journal* of August 3rd (p. 228). The Principal is one of the most distinguished Scotsmen of the time, and has been honoured by many of the important universities of the world. His academic career is an unbroken record of brilliant achievement. He was born at Perth in 1854, and is the son of the late Mr. Donald MacAlister, formerly of Tarbert, Loch Fyne, Argyllshire. Having received his early education at Aberdeen, he went to Liverpool before entering St. John's College, Cambridge, and in those early days were developed gifts of mind and character which were to carry him to eminence. Senior Wrangler and First Smith's Prizeman at Cambridge, he was elected a Fellow of his College, and afterwards became tutor and director of medical studies there. Later he was Lecturer in Natural Philosophy at St. Bartholomew's Hospital, London, and in 1899 he became Thomson Lecturer at Aberdeen. For many years he represented Cambridge on the General Medical Council, and in 1905 he succeeded Sir William Turner of Edinburgh in the presidency of that body. His appointment to the Principalship of Glasgow University in 1907 broke the line of divinity principals. He succeeded the Very Rev. Principal Story. Combined with his eminence in arts and science, and his deep and varied scholarship, Sir Donald MacAlister has great business aptitude and capacity for organization. His tenure of high office at Gilmorehill will be memorable, probably historic. He saw the foundation of many new chairs and lectureships, among them being the chairs of obstetrics and gynaecology, surgery, medicine, and pathology, at Glasgow Royal Infirmary; and at the University the chairs of Scottish history and literature, French, German, bacteriology, organic chemistry, mercantile law, and applied physics. Sir Donald MacAlister has a long list of publications to his name, including a translation of *Ziegler's Pathological Anatomy*. A master of tongues, he speaks no fewer than fourteen languages with fluency. The appointment of a successor to the Principalship will be made by the Crown authorities.

Neglect of Pharmacology.

In view of the presidential address delivered on July 24th at Capetown by Professor W. E. Dixon before the Section of Physiology, British Association, of which a full abstract appeared in the *British Medical Journal* of July 27th (p. 138) and which was commented upon in a leading article in the same issue (p. 151), an address by Professor A. J. Clark, of the department of pharmacology, University of Edinburgh, to the Edinburgh Rotary Club on July 18th, is of interest. Professor Clark, after tracing the growth of synthetically produced drugs, said that about thirty years ago the "nihilist" idea was dominant. People said that drugs were things of the past, but that was just the end of a period, when the sciences of physiology and bacteriology had reached their full development, and the science

of pharmacology had not yet started. The importance of pharmacology to-day was best seen by the number of new drugs which had been discovered in the last twenty years. The revolution which had occurred in connexion with tropical diseases was most significant. The real value of the drugs could hardly be overestimated; they were factors in the development of tropical countries. A large number of drugs of high therapeutic utility had also been discovered. But whereas in physiology Britain had very much led the world, in pure pharmacology they could not claim anything like such success. Unhappily, in the discovery of new drugs Britain had definitely lagged behind. The reason was that the production of those drugs required very big organized laboratories. That kind of team work existed in Germany, and had been very largely fostered by the great German chemical firms, but it did not exist in this country, and the result had been that they had not really taken their share in that particular line of investigation, which there was every reason to suppose would be even more important in the future than in the past.

Death Certification in Scotland.

The Registrar-General for Scotland has issued a leaflet intimating to medical practitioners that an alteration of the statutory form of medical certificate of cause of death has been approved by an Order in Council dated June 8th, 1929, and that the new form of certificate supersedes that now in use and should in future be used for all deaths in Scotland. The change consists in the insertion of a panel at the bottom of the schedule stating that in future, when certifying the cause of death of a married woman, if the certifier is aware that the deceased was either pregnant at the time of death or was pregnant four weeks previous to death, it will be his statutory duty to enter the word "Yes" in the appropriate place on the certificate. This requirement will not apply when certifying the death of an unmarried woman or widow. Negative answers are not required. Whenever pregnancy, parturition, or miscarriage has been in any way a contributory cause of death, the fact should be mentioned in the main portion of the certificate, regardless of whether the special pregnancy question has been answered or not. For instance, a death from puerperal eclampsia or puerperal septicaemia or postpartum haemorrhage should be so described, and not merely described as "eclampsia," or "septicaemia," or "haemorrhage." The additional information now required will not be inserted by registrars in the death register books, and will not appear in extracts or certificates issued by registrars. It will be conveyed to the medical officer of health for use for public health purposes, more particularly in connexion with a special study of maternity mortality. Medical practitioners should at once obtain supplies of the new form of certificates from their local registrars, and stocks of unused old forms should be destroyed. If any practitioner has difficulty in obtaining a supply of the new forms he should communicate with the Registrar-General, Dr. J. C. Dunlop, New Register House, Edinburgh.

Perth Doctor Honoured.

In recognition of the many public services rendered by him to the city and county generally, and in particular to the Hillside Homes, which were in a large measure brought into being in 1876 through the efforts of his father, Dr. Robert Stirling was, on July 24th, presented with his portrait in oils and a cheque from upwards of 600 subscribers in Perthshire. The ceremony, which took place in the Station Hotel, was attended by a large and representative gathering. Mr. David Martin of Keithbyhead, Auchterarder, convener of the committee in charge of the arrangements, occupied the chair in the absence of the Earl of Moray, and the portrait, which was the work of Mr. Fiddes Watt, R.S.A., was presented by Mr. F. Norie-Miller, J.P., of Cleeve. In the course of his reply, Dr. Stirling recalled in a most interesting way the changes in medical thought and practice which had taken place in the course of his professional life, referring in particular to bacteriological, radiological, and public health developments. He thought that in the future the State would have to subsidize the voluntary hospitals, but hoped that in the extension of State and municipal control the poor practitioner would not be left altogether out in the cold. He concluded by affirming his affection for Perth and Perthshire, and said that it had always been his endeavour to advance the fair name of his native city.

Visit of Continental Doctors to Edinburgh.

On August 1st the Lord Provost, magistrates, and town council of Edinburgh entertained about 320 members of a party of Continental tourists at a garden party in the grounds of Lauriston Castle. The guests were composed of doctors, medical students, and their relatives, together with a small number of tourists not attached to the medical profession, and were completing a holiday cruise under the auspices of the *Bruxelles-Médical*. The majority were Belgian and French, but the party included also Swiss, Italian, Spanish, Rumanian, Czechoslovakian, Dutch, and Egyptian members. Leith was their last port of call before returning to Bordeaux, and they had already visited Norway, the Faroe Islands, and Shetland. Lord Provost Sir Alexander Stevenson extended a welcome to the guests, which was acknowledged by Professor Ley of Brussels University. During the afternoon the Edinburgh City Police Pipe Band played selections on the lawn, and this part of the programme excited much interest and enthusiasm. During the course of the day a number of the medical men in the party visited Edinburgh Royal Infirmary. A visit was also paid to the Scottish National War Memorial, where a wreath was laid, and to the Palace of Holyroodhouse.

Ireland.

Health Services in the Irish Free State.

CONSIDERABLE progress has been made with the appointment of medical officers of health in the Irish Free State. Dr. Stephenson, chief medical officer of the Department of Local Government and Public Health, stated recently that in addition to the six counties which have county medical officers already installed, advertisements have been issued for such officers for Donegal and Meath. The Local Appointments Commission, he said, are also being asked to recommend suitable persons for the position in the counties of Limerick, Monaghan, and Wicklow. The question has been under consideration in Galway, Kerry, Roscommon, Leitrim, and Wexford, where appointments will also be made shortly, and it is being raised in Leix, Waterford, and other counties. The appointment of a county medical officer of health in every county is now a matter of urgency, as, in addition to epidemiological and the other public health problems that have been urged from time to time, it is felt that the successful administration of the Milk and Dairies Bill, which will be shortly introduced, and the efficient supervision of the meat supplies, can best be achieved by a whole-time trained sanitarian. When the arrangements now pending are completed more than half the State will have been organized, and it is expected that the example set by these counties will hasten the adoption of schemes by the others. Dr. Stephenson said the attitude of his department was that a uniform health service throughout the State was essential, and that it was obvious that the adoption of analogous schemes by the remaining counties could not be allowed to be delayed. School medical service is being developed in each county concurrently with the appointment of county medical officers. Waterford is the only county borough now in which medical inspection of school children has not been undertaken. Considerable progress has been made with the schemes in Dublin and Cork county boroughs, in Clonmel urban district, and in the counties of Cork, Kildare, Louth, and Offaly.

Tuberculosis in County Wexford.

Dr. W. O'Connor, tuberculosis medical officer, in his annual report to the County Wexford Insurance Committee, draws attention to the following facts. The number of cases of insured persons who had been treated was eighty-seven; forty-four cases proved to be non-tuberculous. He remarks that as regards the occupations of these patients labourers (agricultural and urban), ex-soldiers (most of

whom were previously labourers), and domestic servants constitute by far the largest number; these comprise the principal occupations in the county. No special evidence of tuberculosis is shown in any particular part of the county more than another, except in so far as determined by density of population—namely, in urban areas, as contrasted with rural. Possibly there is less tuberculosis in the north-west part of the county. As has been the case hitherto, bad home conditions, and small crowded houses, unemployment or irregular work, with consequent undernutrition, tend to lower the vitality and favour the development of tuberculosis. In rural districts the long journeys of underfed and insufficiently clad children to schools have a bearing on the propagation of tuberculosis. It may not be possible to distinguish between direct and indirect infection; both may occur, but indirect infection is more frequent. Where considered necessary, cases, chiefly surgical, are sent to a Dublin hospital for *x*-ray examination, there being no apparatus in the county. The need exists for a continuation of sanatorium treatment beyond that usually given—about six months. This period is not often sufficient to restore working capacity, and, when it does, the patient is likely to fail under conditions involving hard work. To complete treatment, reliable settlements or colonies are required. These could serve a group of counties, and might be made to some extent self-supporting. Dr. J. J. Hogan, tuberculosis officer, Waterford, in his annual report, states that last year's figures represent a reduction of nearly 60 per cent. in the death rate from tuberculosis as compared with 1919.

Vaccination in Wexford.

At a recent meeting of Wexford corporation letters were read from the Department of Local Government and Public Health, requesting that energetic action be taken to ensure that all defaulters under the Vaccination Acts would comply with the law. The town clerk said that in his last report Dr. Pierse stated that there were 2,679 defaulters, and that the amount of vaccination performed was not in proportion to the population. Dr. Pierse had served a hundred notices on people who had not had their children vaccinated, and the result was forty-nine complied, thirteen children were proved unfit for vaccination, and two defaulters had left Wexford, but had promised to have the children vaccinated in their new abode. That left only thirty-six defaulters out of the hundred, and the town clerk thought that this was very good.

England and Wales.

Medical Arrangements for the Jamboree.

ALTHOUGH some 15,000 scouts from foreign countries are now visiting England, and more than 50,000 are in camp together near Birkenhead, there has been a surprisingly small amount of sickness and very few serious casualties. To these figures must be added the many thousands of visitors of all ages who have free access to the encampment during the day. The highly gratifying freedom from illness must undoubtedly be attributed to the elaborate medical and sanitary organization which has come into being. In the main camp at Arrowe Park, which contains some 30,000 scouts, large areas of woodland alternate with undulating slopes, and even during the drought there were several stagnant pools. Energetic steps were taken in advance by the local public health authorities to free these pools from insect infestation, and the success achieved in this respect is an outstanding feature of a carefully planned scheme. Well-constructed latrines are disposed in sufficient numbers and at suitable spots, and their emptying and cleansing has been placed in expert hands. The water supply was thoughtfully planned, and energetic measures are in operation to prevent waste. So far as possible all the boys underwent a medical examination before coming to camp, and, in the case of the foreign contingents, clearance certificates were issued at the British ports and elsewhere. The health organization of the camp in Arrowe Park is in the hands of Major M. B. H. Ritchie; it comprises the medical staffing of nine sub-camps; consulting physicians for general medical conditions, and for such specialties as dermatology, tropical diseases, pathology, and infectious diseases; consulting surgeons, orthopaedists, ophthalmologists, and oto-rhino-laryngologists; dentists; a hygiene advisory council: a staff for the improvised hospital; and a large number of public first-aid posts under medical supervision. The hospital contains four marquees, each with fifteen beds; one ward is reserved as a "silent ward" for head injuries and cases of severe shock. Another marquee has been fully fitted as an operating theatre, thanks to the generosity of several leading surgical instrument firms. A well-equipped dental department has been in constant use. Bell tents have been set apart for isolating cases of suspected infectious disease, and have enabled the medical officers to stamp out threatened outbreaks of scarlet fever, diphtheria, and chicken-pox. The hospital is in the charge of Lieut.-Colonel J. C. H. Leicester, I.M.S.(ret.), and is administered and staffed by the Cheshire Girl Guides, under Miss M. C. Royden, the majority of whom have received full V.A.D. training or served as nurses during the war. All the arenas and open spaces of the vast camping ground are patrolled continually by members of the St. John Ambulance Brigade and the British Red Cross Society; a fleet of motor cars is kept ready to convey any serious cases to hospital, and all the units are linked together by telephone. The hospital, with its seventy-two beds, has on one or two occasions been more than filled, but the local hospitals of Birkenhead and Liverpool are co-operating whole-heartedly, and deal with all cases which cannot conveniently be kept in camp. The elaborate organization is working with the utmost smoothness, and the collection and evacuation of cases is proceeding with exemplary rapidity. Since very many of the foreign scouts have desired to spend some time in London before or after the Jamboree a rest camp has been established in the buildings of the Earl's Court Exhibition, where a first-aid post is operating night and day under medical supervision. Here, again, outside institutions are co-operating cordially, in particular the West London Hospital and the Metropolitan Asylums Board. Apart from accidents the chief anxieties are infectious diseases, and such acute conditions as pneumonia; all emergencies are being dealt with effectively. The adverse weather conditions have caused very little illness up to the present; the very manifest cheeriness of those in camp witnesses to their soundness of body in spite of the morasses of mud which for a time defied the efforts of large parties of sanitary workers and road makers. The inevitable digestive disturbances resulting from the unaccustomed dietaries to which some of the foreign scouts had to adapt themselves have proved amenable to treatment.

Epsom College.

The seventy-sixth anniversary of Founder's Day was celebrated at Epsom College on July 27th. The council entertained 150 guests at luncheon, and more than 1,000 parents and friends were present in the afternoon, when Lord Eustace Percy gave away the prizes. Addressing the boys, he insisted that the essential point in what was implied by the word "education" was the quality of understanding men and women. General education meant acquiring the ability to know and understand other people and to sympathize with them. The world would not necessarily fail if specialists were lacking, but it might very well fail if there was a deficiency of people with simple human understanding and the power of handling others. They constituted the cement which kept society together, and in this country to-day there was a special need of such cement. The headmaster reported a large number of successes in school examinations and a good cricket season. There had been continued progress in other branches of athletics, and an open sizarship had been won at Cambridge. He paid tribute to the memory of Lord Rosebery, who had been president of the College for twenty-nine years; to Dr. de Havilland Hall, who had been vice-chairman for very many years; and to Mr. Aeneas Mackay. Dr. Raymond Crawfurd, chairman of the council, who moved a vote of thanks to Lord Eustace Percy, commented on the material progress that had been achieved at the school.

The scale of masters' salaries had been considerably increased during the present year, additions had been made to the dietary, and various improvements effected for the well-being of the boys. Among these he mentioned particularly alterations in the swimming bath, including the provision of an electrolyser for disinfection; the building of a new changing room in one of the houses; the utilization of Lord Beaverbrook's donation for the furtherance of scientific education; and the provision of a new cricket practice pitch. Improvements planned for the immediate future were the building of a new rifle range which would be capable of accommodating eight marksmen abreast, and considerable structural alterations at Wilson House. Dr. Crawfurd hoped that the building of the new sanatorium would not be long delayed, since, with its completion, the council could consider that their main plans for enlargement had been brought to a successful conclusion. A two-day cricket match resulted in a decisive win for the College against an "Old Epsomian" eleven. In the evening the College Dramatic Society gave a very successful performance of Bernard Shaw's *St. Joan*.

Complimentary Dinner to Dr. Morris-Jones, M.P.

Dr. J. H. Morris-Jones, who represents the Denbigh Division in Parliament, was entertained by the Colwyn Bay and District Medical Society to a complimentary dinner on July 19th. This Society consists of about thirty medical practitioners, most of whom are members of the British Medical Association. Dr. Morris-Jones, replying to the toast of his health, commented on the great interest of the work which had been undertaken in the new Parliament; special attention was being paid to the various problems associated with road transport generally.

Correspondence.

MATERNAL MORTALITY.

Problem of the Unmarried Mother and Her Child.

SIR,—In the interesting and instructive address given in Nottingham on "The national inquiry into the causes of our high maternal mortality rate," Dr. T. W. Eden says (*Journal*, July 20th, p. 81): "The problem of the care of unmarried mothers is as much a social as a medical problem, and it seems to me that this is a channel into which philanthropic effort might well be guided, for there is surely much to be done, much which cries loudly to be done, in helping these heavily burdened women through the ordeal which is to them infinitely more formidable than it is to their married sisters." It is a terrible reflection that in the number of cases under consideration the mortality from sepsis in the mothers was three times as high as the total maternal death rate from sepsis, and that the maternal death rate of the unmarried mothers was more than double the total rate.

According to the statistical report of the Registrar-General for England and Wales for 1927, there were 29,023 illegitimate children. There are many reasons into which it is not necessary to enter, why the mother of an illegitimate child receives less attention during pregnancy than a married woman. I have had under my care in the hospital an unmarried girl who, left alone in charge of a large house, gave birth to her child unattended, and directly after the birth left her room to answer the front-door bell; she was septic when admitted. I have also known an unmarried mother throw her child on the dust heap to die. These are instances which unfortunately could be multiplied from my own knowledge.

I agree with Dr. Eden that there is much to be done to help these poor women. Some years before the war, when I was in Russia, I tried to do something which I believed would be of service, because I was struck with the fact that the Foundling Hospital at Moscow, a hospital of enormous advantage from a clinical point of view, admitted yearly about 15,000 infants. To that institution any illegitimate child was admitted immediately on presentation, without any question being asked. I do not know what has happened since the war. On my return I spoke to many wealthy people, saying I wanted to raise money to build a foundling hospital which could be affiliated to a lying-in charity, and that, as soon as the unmarried mother recovered from her confinement, if she could not take care of the child, it should be transferred to the hospital. In Moscow the child after a time was sent into the country, and, later, was taught some useful work; but it could always be traced by its registration number. I was listened to sympathetically by women regarding the hospital, but when I explained what I wanted about the foundling hospital, I was told that it was a premium on vice, etc., so that, after taking a great deal of trouble, I had to let the matter drop.

My scheme was to allow girls about to become mothers to be admitted to the lying-in hospital some time before confinement, and that the foundling hospital was to be conducted on the same lines as the one in Russia, admitting infants from the lying-in hospital attached, and also any child presented who was known to be illegitimate. I certainly failed in my endeavour at that time; but perhaps, now that so much interest is being taken in puerperal sepsis and mortality, something substantial may be done. The members of our profession are in touch *with many who are philanthropically inclined, and it would* be a real blessing if we could make some provision for these poor women in their time of trouble.—I am, etc.,

London, S.W., July 30th. R. A. GIBBONS.

TREATMENT OF EXOPHTHALMIC GOITRE.

SIR,—It is difficult for the opposing schools of thought on this question to find common ground on which they can meet. Dr. Don rules out all cases—the vast majority—that have not been submitted to a basal metabolic rate test, whereas Dr. Webster bases his arguments on the very cases that Dr. Don dismisses as "not . . . sufficiently completely investigated." I agree that instruments and methods of precision have their value, but the trained clinical sense of a competent observer who has watched hundreds of cases recovering under *x*-ray treatment is not to be dismissed lightly.

Not to admit a diagnosis of exophthalmic goitre without a metabolic rate test is surely an extreme view, in a disease where signs and symptoms are so distinctive. I take similar exception to the view that metabolism must be proved, by the same method, to be normal, before the patient can be regarded as "cured." I venture to submit that not only is the clinical method perfectly adequate at this stage, but the patient himself knows perfectly well when he is restored to health. The weight goes up as the pulse rate comes down; nervousness and tremor disappear, and the ordinary activities of life are resumed. With results like these, what further evidence is required?—I am, etc.,

F. M. FELLOWS, M.B., C.M., F.R.C.S.Ed.

Poynton, July 28th.

SIR,—It has been truly said of medicine that science is a first-rate furnishing to the upper stories, provided that the ground floor is well stocked with common sense. If a patient who has been bedridden, weeping without cause, nervy to the last degree, and showing one or more of the other stigmata of hyperthyroidism, is able to go about her daily work, and is able to lead an ordinary life which is no longer a burden but a pleasure, both to herself and her friends, then it does not need science to determine that the patient is cured, no matter what the metabolic pulse rate may have been or is. There are probably many sick people who, "scientifically," are perfectly well, and there are, I regret to say, many perfectly healthy people who are ill simply because, according to science, they ought to be ill.

A little knowledge is a very dangerous thing, and medicine is not a science—it is still an art; until we know the secrets of life itself it always will defy all our efforts to make it into a science. Poor weak humanity—it does not know when it is ill or when it is well. It has to be told these things by the doctor, and if he has any clinical acumen or gumption he can, and perhaps will, tell the patient the truth every time, without the aid of metabolic or other tests. Such tests are of great use in supplying us with figures as records that are particularly helpful in

writing papers. Communications with such figures are imposing as compared with those based on clinical data and experience, but it does not follow that the conclusions arrived at are any less scientific or reliable.—I am, etc.,

Cambridge, July 30th. A. E. BARCLAY.

PHYSIOLOGICAL STUDY OF ASTHMA.

SIR,—In my letter of July 20th (p. 121) I pointed out that the type of breathing which affords the maximum respiratory interchange in the lungs is that in which the mean size of the chest is increased and breathing takes about this increased mean. This type of breathing not only secures a maximum respiratory area, but a minimum resistance to the blood flow from the right to the left heart. In order to maximize the mean size of the lungs the deepest possible inspirations are taken, while expirations stop far short of their maximum: full expirations would fail to increase the mean size of the lungs, and would greatly impede the pulmonary circulation.

Accordingly we find that both in physiological breathlessness and in the breathlessness of organic heart and lung disease the chest is expanded and the respiratory movements take place about this increased mean. Inspirations tend to be powerful; expirations (with certain exceptions) moderate. In physiological breathlessness, indeed, expirations are effected by little more than elastic recoil.

Let us now suppose a case in which the bronchioles are narrowed (whether by muscular spasm or urticurial swelling of their mucous membrane) to a degree seriously interfering with the passage of air through them; the chest would expand in accordance with the principles enunciated, inspirations would be violent, while (for reasons given in my previous letter) expirations would be cautious and prolonged.

While admitting that Dr. Watson-Williams's ingenious hypothesis would explain in a neat and seductive fashion the phenomena of the asthmatic attack, I suggest that my explanation brings the pathology of asthmatic breathing more into line with other types of dyspnoea than Dr. Watson-Williams's view, attractive though it be.

The effective expansion of the collapsed lungs of the newborn baby is, as Dr. Watson-Williams observes, facilitated by obstructing the easy exit of expired air. Such obstruction, he suggests, is afforded by an (exaggerated) expiratory contraction of the bronchioles; but he omits to take into consideration what I conceive to be a much more effective mechanism for securing adequate expansion of the collapsed lungs—namely, the baby's lusty cries; the forcible expirations thus resulting, by increasing intrapulmonary air pressure, provide, I suggest, a more effectual means of opening up collapsed vesicles than that advocated by Dr. Watson-Williams.—I am, etc.,

London, Aug. 1st. HARRY CAMPBELL.

GENERAL CONVULSIONS UNDER ETHER.

SIR,—Since first describing general convulsions occurring under surgical anaesthesia in the *British Medical Journal* (May 28th, 1927, p. 956) a number of correspondents have discussed in your columns their experiences, and I should like now to restate my views in the light of subsequent manifestations of this rather obscure phenomenon.

The advice as to treatment which I originally gave I have found completely successful, so that though I have little doubt that deaths still sometimes occur (and several have been reported since I wrote), I have had no more. I believe it well, therefore, to repeat this advice. It is necessary to recognize the very beginning of the spasm, and immediately remove all coverings and sources of vapour away from the face, giving free access of fresh air. The recovery from the anaesthetic is delayed in cases where the convulsions have been well established, but if any more anaesthetic is needed then it should be chloroform.

Many suggestions have been made as to the cause of the convulsions: I am quite sure that it is not due to some decomposition or impurity in ether. These impurities exist in very small quantities, and though often accused of various offences, have never been convicted by a majority of anaesthetists. In the Clover inhaler and its modifications, so much used a few years ago, where the ether had an excellent chance of decomposition, no cases were reported. For many years methylated ether was used exclusively at the Royal Infirmary here, before a case was noticed; moreover, without doubt, our ether is generally purer now than formerly, not less pure. Many cases have occurred where fresh bottles of a good brand had been used by a method which precludes the theory of decomposition subsequent to opening them. One such I remember witnessing where the ether was poured on to lint without decanting it into any other bottle. Though isolated cases may tempt one to this hypothesis, there is scarcely any real evidence in favour, and plenty against.

The "bomb" apparatus has been blamed, but so many cases have occurred without it that it cannot be that. In the last case that was reported to me ether was given by the Shipway apparatus; the patient was a boy, and he died. It is said that the bomb apparatus, which I have used continuously for the last ten years, is likely to decompose the ether. Perhaps it is, but, if it does, the products formed are harmless, or I would not be using it now. In the last case but one that I had, I made an experiment; I returned to ether from the bomb, after the convulsions, which had rapidly been advancing, had subsided, and before the operation was half done. In this case the above theories (of decomposition or impurities) were to some extent put to the test: convulsions did not recur, and there was no ill effect.

My view is this, after seeing a considerable number of such cases (almost twenty): it is the method which is at fault—the way the patient is handled; anaesthetists will know what I mean. It is not the ether itself (or anything in the ether), but something besides. I believe the breathing is earliest affected, and that this is directly responsible for an extension of irregular muscular action from the respiratory muscles to those of the rest of the body; and when I repeat that it is an excess of CO_2 which affects it, I mean in conjunction with the other factors—etheration, toxaemia, pyrexia, idiosyncrasy, and, perhaps not least, an excess of oxygen. Usually an excess of CO_2 in the blood has been manifested by a corresponding anoxaemia, but nowadays that is not allowed to occur; so that accumulation of it would be marked by the good colour. We cannot always handle or guide a patient as we could wish; but are sometimes forced, by his reaction to it, to push the anaesthetic, as it were, into him, cover his face with towels, or otherwise adopt measures which we might not have desired. These methods, I suggest, are the cause of a state of things the outcome of which is general convulsions.—I am etc.,

Manchester, July 23rd. K. B. PINSON.

GAS-OXYGEN ANAESTHESIA.

SIR,—I have inquired of many students from various hospitals and have found none who have been taught gas and oxygen anaesthesia. Dr. Slaughter (July 20th, p. 124) seems to have a very poor estimate of my opinion, so I will quote others which may possibly carry more weight.

I received this week an article entitled "Anaesthesia in thoracic operations," by C. Langton Hewer, M.B. It is marked "With compliments, v. pp. 78–79." On referring to page 78, I find specially marked:

> "Apparatus: The type of apparatus employed will naturally depend on the preference of the individual anaesthetist and upon local conveniences. If expense and portability are of no object, the elaborate American machines such as the Hiedbrink and McKesson are very efficient and permit of very fine mixture control. For ordinary use, however, a much simpler and more portable sight-feed apparatus can be used with every satisfaction. The writer employs a Boyle's machine with a modified sight-feed as shown."

Evidently Dr. Hewer considers Boyle's machine inferior to the American ones, but uses it on account of expense and portability. The reason I use my machine is solely on account of efficiency—no other reason counts with me. The argument about portability will not stand, because the portability of all gas machines is limited by the gas cylinders, and whatever machine is used these are an unavoidable drawback. I do not like the argument of expense when imported into a medical discussion, as it savours of commercialism; still, even that is not altogether in favour of Boyle's apparatus. When it is realized that

an efficient machine uses only about two-thirds the amount of gas an inefficient one does, it will be seen that, though the first cost may be higher, the more expensive may be much the cheapest in the end.

On page 79 of Dr. Hewer's paper I find, under the illustration of the modified Boyle's machine, this statement: "The flow of oxygen remains constant, but difficulty may be experienced in maintaining regularity in the nitrous oxide supply." In an article in the *British Journal of Anaesthesia* for April, 1929, by S. Thompson Rowling, M.D., the author points out the difficulty of regulating a "bubble bottle." I was at the British Medical Association meeting at Manchester and saw Dr. Rowling demonstrating his apparatus; I pointed out that the oxygen was not flowing regularly. Dr. Rowling admitted that it was not, but said there was some defect in the machine. I thought it curious to show a defective machine at an exhibition. I don't apologize for mine: it "delivers the goods." With regard to the nitrous oxide flow, Dr. Hewer says it is difficult to control. I go further and say it is impossible with the machine he uses.

Turning to page 74 of Dr. Hewer's paper, I find that he says:

"In war surgery of the chest, where patients have been badly shocked, there is no doubt whatever that many lives have been saved by operations performed under nitrous oxide-oxygen anaesthesia which would be regarded as hopeless if attempted with other methods. The above remark must be taken to apply to pure nitrous oxide-oxygen anaesthesia only; if ether or chloroform be added to the gases, even in small amounts, toxic effects may ensue."

And yet Dr. Hewer uses and teaches students with a Boyle's machine in which the gas control is so bad that ether has to be added in more than 60 per cent. of cases, when he knows and admits there are better machines to be obtained, and, mark you, because of expense and portability. I think I need comment no further on this point.

Dr. Slaughter says an emergency oxygen valve is not essential. I would much appreciate Dr. de Lacy Walker's views on this. In my opinion (for what it is worth) it is a most vital fitment to have, because gas deaths are from asphyxia in the vast majority of cases; and although gas is the safest anaesthetic known, yet it is a great comfort to know that you have oxygen under pressure at your instant call. Already this letter is too long, but I suggest that if cheapness and portability are the chief objects to be sought, nothing compares with a bit of rag and a chloroform bottle.—I am, etc.,

E. J. CHAMBERS.

Doncaster, Aug. 3rd.

SIR,—Sometimes the evidence of a bystander may be as useful as that of a principal performer, and I, having been privileged to see 100 operations done under gas and oxygen, given by one of the protagonists in the discussion about that anaesthetic, can contribute an onlooker's point of view.

My notes give the actual cases as follows:

Cholecystectomies	4
Partial gastrectomy	1
Gastro-enterostomy	1
Renal calculus	1
Radical amputation of breast	2
Resection caecum	10
Appendix	7
Hernia	18
Gynaecological, including 3 hysterectomies	11
Bone operations	3
Prostatectomies	41
Miscellaneous	100

These operations were performed by a series of seven surgeons, in this and other towns, and they expressed themselves as satisfied with the access obtained. The apparatus used was that of McKesson, which allows very delicate control of the proportions of the mixture.

In only nine of these was any other given, three times to carry on while cylinders were being changed, three times in mouth cases because difficulty was experienced with the Kuhn's tube, and in three cases to save a few minutes, as some patients require more time for relaxation than others. In most of 38 tonsillectomies (not included in the 100) ether was given simply to afford that surgeon a little longer grace after the mask was removed.

Of the 100 cases, 2 only, appendices, were emergencies, but they differed in no way from the rest. If any lack of relaxation were anticipated it was forestalled by the use of a few cubic centimetres of local anaesthetic before the incision, and the little extra trouble was quite compensated by the increased well-being of the patient. In this series bleeding has never appeared more copious than with any other anaesthetic, and it is worth while in this respect to refer to Dr. Kelly's article (August 3rd, p. 187), where he suggests that deficient haemorrhage is the result of only one condition, and that a dangerous one—namely, "extremely low blood pressure."

A peaceful induction, a quiet maintenance, a quick recovery without vomiting, and a grateful patient afterwards, appear the chief features of a gas-oxygen anaesthetic as I have seen it. As to the label of "routine anaesthesia," words are less important than facts, and surely no one would wish to expose any patient to a more toxic drug than another simply to escape the reproach of monotony. Besides which, this method can provide quicker control and finer adjustment to the needs of a particular case than any other, at the present stage.—I am, etc.,

B. E. COOK, M.B., Ch.B.

Doncaster, Aug. 4th.

TREATMENT OF PLACENTA PRAEVIA.

SIR,—I attended to-day the meeting of the Gynaecological Section at Manchester and listened to two papers on placenta praevia and its treatment. The discussion which followed resolved itself into a wrangle on the merits and demerits of Caesarean section as the treatment of choice. More than half our time was wasted on this account. All the speakers, with one exception, the chairman, seemed to forget the fact that the early diagnosis of placenta praevia depends entirely upon the general practitioner. He it is who first sees the condition and first diagnoses it (and this he can do without per vaginam examination), and he therefore should be the one to apply the correct treatment at the earliest possible moment.

The meeting agreed that immediate action was imperative, but instead of helping the general practitioner by discovering and discussing the best treatment to apply at this juncture, those who are supposed to know most about the condition wasted valuable time airily discussing Caesarean section. Dr. Solomons told us that it is impossible to make a diagnosis without per vaginam examination, and he and others emphasized the fact that this examination caused the sudden onset of haemorrhage. The patient is examined at home, again on admission to hospital, and again by the gynaecologist before he takes his "immediate action." That is, she is subjected to at least three examinations, by each of which her chances are lessened enormously, not only by the loss of blood, but by concomitant shock and exposure to sepsis. Added to all this there is the conveying of the patient from her home to hospital. If she arrives there alive, there is possibly nothing else for it but Caesarean section! To my mind this is all wrong. The most important factor in the successful treatment of haemorrhage from any part of the body, uterus included, is absolute rest, and if this is kept in mind the question of Caesarean section fades immediately out of the picture.

Placenta praevia is not generally recognized until the last four weeks of pregnancy, when haemorrhage sets in, and I should like to submit a simple remedy to the highbrows, a remedy which is well within the scope of the average general practitioner, and is easily and quickly applied. It is intramuscular injection of ovarian residue without corpus luteum. This is of use only after the eighth month. I have used this as a routine in the first and second stages of all my midwifery cases for the last three years. Labour is shortened enormously, relaxation is so complete that delivery with forceps is easy, and laceration rarely occurs. Post-partum haemorrhage loses its terrors because it does not occur. Recovery is rapid, and the milk supply increased. Without exception every multipara says immediately afterwards, "I have never felt so well."

Now, Sir, with regard to the application to placenta praevia, I should like to give details of one of my cases.

Mrs. S., admitted to St. Mary's five years previously with placenta praevia, was delivered of a dead child and nearly lost her life from haemorrhage, and was confined to bed for five months afterwards. Her second pregnancy seemed to go on all right until at the eighth month, when she began to have a "show" without any pain. This recurred repeatedly during the ensuing ten days, when I was called in on account of a severe attack of haemorrhage. Without making any per vaginam examination, I gave her 1 c.cm. of ovarian residue immediately, and within ten minutes the haemorrhage ceased and did not recur in any excessive quantity. Uterine contractions commenced at the same time, and to keep these going I gave her 1 c.cm. at intervals of two hours, until she had received eight injections in all.

Eighteen hours after the first injection I examined her per vaginam for the first time. The os was three parts dilated. Expecting every moment the usual gush of blood, I put her under chloroform, ruptured the membranes, confirmed my diagnosis of placenta praevia (which was lateral), applied forceps, and delivered rapidly. I was able to express the placenta almost immediately. The puerperium was uneventful, and the patient was up on the tenth day.

—I am, etc.,

Manchester, July 25th. D. C. MACDONALD, M.B.

BREAST-FEEDING BY TUBERCULOUS MOTHERS.

SIR,—Dr. P. J. Burke states, in your issue of July 20th (p. 123), that he is guided by circumstances in his advice to tuberculous mothers as to whether they shall breast-feed their babies, if the mother is his main consideration; and advises breast-feeding if the baby is his concern.

Both mother and baby can be well advised in this respect if the teaching of Professors Léon Bernard and Robert Debré be followed, and this is based on long and scientific research data at the Laennec Hospital, Paris. They allow nursing, but take precautions as to contact. At the crèche the mother has her face covered with a linen mask, wears a sterilized blouse, and has her hands washed before the child is put to the breast. The mother is allowed to feed her baby on the bottle only if she suffers in health herself from suckling (*La prophylaxie de la Tuberculose à l'âge pré-scolaire*, pp. 42, 48, and 54: Third International Congress against Tuberculosis, Brussels, 1922). Again, they say in the *Annales de Médecine*, Tome xiii, No. 5, Mai, 1923 (p. 396), that it is only the intimate contact of the mother with her baby when she fondles it, kisses it, plays with it, and takes it in her arms which is responsible for infection; and breast-feeding only increases the risk by closer and more frequent contact.

This method of infection is one only in the grave national problem of the prevention of tuberculosis in the home, and the need for a universal public health system and tuberculosis schemes which would offer to parents or others the opportunity of separating infants and children from home sources of infection, especially from the massive and repeated doses from tuberculous parents or others who are receiving domiciliary treatment in overcrowded tenements. At present we carry out the costly ritual throughout our tuberculosis dispensaries of examining "contacts" and advising the public not to let themselves or others get infected, but we offer no practical means of prevention as do the French nation. We should actively advise infective parents to allow their children to be separated in a home, either collectively, as in a residential open-air school or home (as in Plymouth), or by "boarding out" as in France.

What is the policy of the Ministry of Health? In June it informed me: (1) That it has no power to make grants in respect of maintenance of "contact" children (which I doubt, but which should be remedied). (2) That its policy is to remove advanced cases of consumption to hospital, thus segregating the patient rather than the contact. To which I ask, How many infective consumptives are compulsorily removed to hospital? What proportion of the duration of lives of all infective consumptives in this country is spent in hospital, and what at home under domiciliary treatment? A minute percentage of time only, so that the Ministry's policy and practice do not coincide. (3) Lastly, the Ministry says its policy does not exclude a child from being sent to an open-air school or sanatorium if symptoms of "incipient tuberculosis" become evident.

The homely proverb of "A stitch in time saves nine" occurs to those who desire to establish a scientific, sane, and humane system of preventive medicine. We should offer the child its chance of health as well as the parent; the helpless one needs most protection.—I am, etc.,

F. G. BUSHNELL,
Vice-President, Devon and Cornwall Sanatorium for Consumptives.

Plymouth, July 22nd.

IMMUNIZATION BY TUBERCULIN.

SIR,—With reference to Dr. Carswell's letter (July 20th, p. 123) I claim no general superiority for exotoxic tuberculins over Koch's emulsionized and more perfected preparations. These latter, seeming to approximate more ideally to the natural toxins *in vivo*, especially commend themselves in the later stages of immunization. Personally I like to use B.E. as an additional, or finishing, course, when the usual one (terminating, arbitrarily perhaps, at 1 c.cm. O.T. human) appears, after a definite interval, to have given insufficiently good results. But, for *commencing* a course, I do prefer P.T.O. because, being a bovine filtrate and containing no endotoxins, its toxicity is weak compared with other tuberculins. This saves excessive diluting. Also the chief consideration, when starting to beleaguer the entrenched bacilli, is to keep focal inflammations at a minimum, and so to avoid as far as possible necrosing those degenerating cells, which form, as it were, the no-man's land between healthy vascular tissue and the dying or already dead products of the tubercle. At this stage careful mining work will, I feel sure, regain more of this damaged tissue than fierce onslaughts, which tend rather to repeat the errors of 1891. Here, as always, "Well begun is half done." Later, when the body has grown used to tuberculin, attacks may be vigorously and successfully pressed with the more potent preparations.—I am, etc.,

Weymouth, July 30th. H. C. MANNING.

PERFORATION OF A GASTRIC ULCER IN A SEPTUAGENARIAN.

SIR,—I have been interested to read the accounts of the successful operations for perforated gastric ulcer in patients aged 70 years and over, reported in the *Journal* of July 20th and of July 27th, and would like to add to them a case I had under my care some years ago.

On July 15th, 1922, I was called out at 7.15 a.m. to see Mr. M., aged 71. The history was that at 1 a.m. he had been seized with acute abdominal pain, which was so severe that some time later his doctor was called in and he was given morphine (grain 1/2). When I saw the patient he was very drowsy and made no particular complaint of any severe pain. Abdominal tenderness was not marked, and the man's chief inclination seemed to be to go to sleep; this made it exceedingly difficult to get a clear history or to arrive at a definite diagnosis. After much trouble I elicited that for many years there had been considerable pain and discomfort after food, and that the day previously the pain had been much worse than usual. An attempt was made to do some work in the garden to see if it would relieve the "indigestion"; this did not give any relief, and, as already noted, the pain went suddenly worse at 1 a.m., after retiring to bed.

I diagnosed a perforated gastric ulcer and had the patient removed to a nursing home. At 10 a.m. I opened the upper abdomen through a right rectus muscle-splitting incision, and found a moderate-sized perforation of a chronic ulcer on the anterior wall of the stomach near the pylorus. There had not been a great deal of extravasation of the stomach contents into the peritoneal cavity, and there was not much general soiling, probably partly due to the large dose of morphine which had been given. The perforation was sutured with thread sutures, and overlapped with a piece of omentum. After the abdomen had been sponged out it was closed without drainage. The patient stood the operation well, but for some days afterwards he gave us a certain amount of anxiety as he became very "chesty." The condition of the lungs, however, gradually cleared up under appropriate treatment, and about a week after the operation he was on the high road to recovery. From this time complete recovery was uneventful, and the man left the home a little over two weeks after the operation.

About two years ago I heard from the patient's doctor that there was some slight recurrence of symptoms suggesting ulcer, but apparently this passed away with medical treatment. The man is still alive and in fairly good health over seven years after the operation, and is able to lead a moderately active life.—I am, etc.,

Manchester, July 29th. GILBERT B. WARBURTON.

SIR,—The case of recovery after operations for gastric perforation on two occasions between the ages of 78 and 81 years described by Professor Fullerton in the *Journal* of July 27th (p. 165), must, as he says, be unique. I was interested also to read the accounts by Mr. J. Price on July 20th (p. 100), and of Mr. R. F. Bolt on July 27th (p. 165) of perforation of gastric ulcer in septuagenarians followed by recovery after operation. The following case may also be of interest.

A man, aged 73, had previously suffered from occasional slight indigestion for which he had never consulted a doctor. At 2 p.m. on September 5th, 1928, while at work, he was suddenly seized with intense epigastric pain. He had had no food since breakfast at 8 a.m. With great difficulty he walked a distance of over a quarter of a mile to the hospital, and was found lying doubled up on the doorstep in a state of collapse. He was in great agony and pouring with cold, clammy sweat; the pulse was imperceptible, and the abdomen was immobile, intensely rigid, and tender. Morphine gr. 1/4 and atropine gr. 1/100 were given, and he was kept very warm. He rallied somewhat and was operated on one hour later. Anaesthesia was induced by gas and oxygen, followed by open ether. A thickened and indurated area with a small perforation was found on the anterior surface of the first part of the duodenum. The edges of the perforation were friable and rigid; a portion of omentum was therefore plugged in and sutured over. The pelvis was drained for twenty-four hours. The patient made a smooth recovery, and left hospital in three weeks; since then he has been in good health, and makes no complaint.

The points of interest in this case are: (1) There was little or no history of previous gastric trouble, though the ulcer was obviously of old standing. (2) The man managed unaided to walk a distance of a quarter of a mile after the perforation had occurred.—I am, etc.,

B. SOUTAR SIMPSON, M.B., F.R.C.S.Ed.,
Surgeon to the Lawson Memorial Hospital.

Golspie, Sutherland, July 30th.

MEDICAL WOMEN AND THE BOARD OF CONTROL.

SIR,—*In your issue of July 13th (p. 64)* you report the appointment of a new "temporary" medical man commissioner to the Board of Control. This brings the number of salaried medical men commissioners to four, two being "temporary." I understand that temporary means "pending further legislation," or for an estimated period of two or three years. In addition, there are one medical man commissioner unpaid and four salaried medical men inspectors, of whom one is "temporary." Thus the number of medical men on the Board totals nine, while, despite the fact that on January 1st, 1928, the number of female patients notified insane exceeded the number of male patients by 12 per cent., not a single medical woman has yet been appointed to the Board of Control.

It appears that the new appointment (of Dr. Bedford Pierce) was arranged by the late Government. Sir Richard Luce, a member of Parliament during its tenure, promised last autumn that he would look into the matter of the then Government's neglect to appoint a medical woman, and the British Medical Association has expressed itself in favour of such appointment. One would like to know what Sir Richard Luce did in the matter, and what the Association has done to substantiate its views. The non-appointment must primarily be a question of sex prejudice and not even of money, for, since there is an honorary medical man commissioner, there can be no objection to appointing an honorary medical woman commissioner. Moreover, in 1928 the income of the Board ran to £746,094.

I appeal to the present medical members of Parliament (numbering seventeen)—of whom nine are Labour, and therefore must have influence with the present Government—to rectify this slight upon medical women and the lack of consideration shown to those female patients and women relatives who may prefer to have medical women commissioners to whom to refer—I appeal, I repeat, to our medical members of Parliament to arrange forthwith for the immediate appointment of at least two medical women commissioners, one salaried and one unsalaried. Are we women never to be free of the wearisome and unpleasant job of perpetually pushing the rights of our sex?—I am, etc.,

Braunton, North Devon, July 30th. C. A. MORTLOCK-BROWN.

Obituary.

JOHN BROWN, M.D., D.P.H.,

Formerly Medical Officer of Health, Bacup, Lancs.

WE regret to record the death of Dr. John Brown, which took place at his home at Blackpool on July 29th; he was in his eightieth year.

John Brown is best remembered for his work as medical officer of health at Bacup, in Lancashire, which office he held for more than one-third of a century. He was born at Callington in Cornwall, and came to London to begin his medical education. He studied at Charing Cross Hospital, where he was [illegible] man of his day, and later at Owens [illegible] University, Manchester. He qualified L.S.A. and L.R.C.P.Lond. in 1877, graduated M.B., Ch.B. Manchester in 1888, and M.D. in 1889, in which year he also took the D.P.H. After holding a house appointment at the Western Ophthalmic Hospital, London, for a brief period, he took up his official work at Bacup, and performed noteworthy services to the town and district in various capacities related to the public health. He was a keen student of chemistry, and interested himself in many phases of sanitary engineering, especially water supplies. He published certain observations on plumbism due to lead-polluted water, a subject on which he spoke in the Public Health Section at Annual Meetings of the British Medical Association. Another publication of his was on tests for colour vision. After his retirement fifteen years ago he devoted himself to the subject of cancer research, and contributed various articles on the subject to medical and other periodicals. His investigation of this problem led to no conclusive results, but his earnestness in pursuing it was most admirable.

He was for many years a member of the Lancashire and Cheshire Branch of the British Medical Association, but in medical politics he was a pronounced individualist. His brother, Dr. George Brown, was for ten years a direct representative for England and Wales on the General Medical Council, and in 1919 Dr. John Brown himself stood for election. He was at the bottom of the poll, with only 1,636 votes, but he declared that this result far exceeded his expectations, for he had no committee nor fund to enable him to circulate the electors. He stated that, having received the support of thirty medical men in Blackpool, he stood as an earnest protest against the action of the British Medical Association in putting forward its own nominees for all the seats, thus practically excluding, in his view, a free election of representatives who were not members of the Association. At the election of direct representatives in 1924 he stood again, with a similar result.

Dr. John Brown carried in his face and demeanour the marks of a personality self-effacing and full of good will. He interested himself in various excellent causes, was an indefatigable worker for charity, and a prominent member of the Wesleyan Methodist body. He leaves a widow and five sons, two of whom are members of the medical profession, both of them medical officers of health; one, Dr. J. Percival Brown, occupies his father's former position as medical officer of health for Bacup, and the other, Dr. George B. Brown, is medical officer of health for Failsworth, Manchester. The funeral took place at Blackpool on August 1st amid many manifestations of regard by the public and the profession.

Medico-Legal.

STATUS OF AN UNREGISTERED PRACTITIONER.

LIEUT.-COLONEL JOHN WILLIAM KYNASTON appeared in both police court and High Court proceedings recently respecting his status as a medical practitioner. The decisions in both courts are of importance to the medical profession and the public in so far as they maintain the disciplinary powers given by the Legislature to the General Medical Council. Lieut.-Colonel Kynaston's name was removed penally from the *Medical Register* in May, 1922, on the ground that he was guilty of infamous conduct in a professional capacity, in that he had sought to attract to himself patients for his own gain by means of advertising. The hearing of the disciplinary proceedings before the General Medical Council was reported in our issue of June 3rd, 1922 (*Supplement*, p. 215). In November of the same year the Executive Committee of the Council was informed that the Royal College of Physicians of London had withdrawn Lieut.-Colonel Kynaston's licence to practise physic, that the Society of Apothecaries had ordered his name to be erased from the list of its Licentiates, and that he had been removed from being a Member of the Royal College of Surgeons of England.

The proceedings at Marlborough Street Police Court began on March 16th, 1929, when two summonses under Section 40 of the Medical Act, 1858, were heard at the instance of the Royal College of Surgeons of England. The first summons, alleging that the defendant wilfully and falsely pretended to be a doctor of medicine, was dismissed by the stipendiary (Mr. Cancellor), who held that there was not sufficient evidence to justify a conviction which could only have been supported by proof of wilful falsity. The defendant was bound over under the Probation of Offenders Act, 1907, on the second summons for wilfully and falsely using the title "M.R.C.S. Eng." in order to pretend that he was registered, the stipendiary finding as a fact that he must have known that the use of the letters "M.R.C.S." would imply that he was still a member of that body.

In the King's Bench Division, Lieut.-Colonel Kynaston sought to make absolute a rule nisi for mandamus requiring the General Medical Council to delete from the *Medical Register* the record of penal removal in 1922. The three judges who constituted the court were unanimous in refusing to make the rule absolute.

The rule nisi had been granted on three grounds. First, Lieut.-Colonel Kynaston complained that his name ought to have been removed by the General Medical Council at his own request in March, 1922, when there were no charges against him. Instead, the Council had retained his name on the *Register*, and in April, 1922, had removed it penally on charges, made by the Medical Defence Union, of infamous conduct in a professional capacity. Upon this, Mr. Justice Avory pointed out that Standing Orders of the General Medical Council required Lieut.-Colonel Kynaston to support his application for the removal of his name at his own request by a declaration that he was not even aware of any reason for the institution of any proceedings for the removal of his name penally. Mr. Justice Branson exposed Lieut-Colonel Kynaston's counsel's argument as amounting to this: that if a medical practitioner desired to do something which he knew was regarded as infamous conduct in a professional respect he might have his name removed, then commit the offence, and then have his name restored! Counsel replied that, if such a loophole existed, his client was entitled to take advantage of it, but the Lord Chief Justice characterized the whole argument as a *reductio ad absurdum*.

The second ground—that Lieut.-Colonel Kynaston's name was erased from the *Register* to discredit a theory of medicine and surgery advocated by him in the publications which were the subject of the charge before the General Medical Council—was held by the court to be an invitation to them to review the conclusions of that Council. It was settled law that the court had no such power.

The third ground was that Sir George Newman ought not to have been present and taken part in the disciplinary proceedings of the General Medical Council in this case, because Lieut.-Colonel Kynaston's criticisms of Sir George Newman had biased and prejudiced him against Lieut.-Colonel Kynaston. In fact, Sir George Newman did not take part in the decision of the Council; but the court rejected the argument that the mere fact that Sir George Newman had been attacked by Lieut.-Colonel Kynaston was in itself evidence of bias. In the words of the Lord Chief Justice, "there was not a tittle of evidence of bias."

The rule nisi was thereupon discharged.

The Services.

COLONEL ALFRED PETERKIN, C.B., Army Medical Service (ret.), died in Queen Alexandra's Military Hospital, Millbank, on July 17th, aged 74. He was born at Slateford, Midlothian, on October 2nd, 1854, the son of Mr. W. A Peterkin of the Board of Supervision, Edinburgh, and was educated at Glasgow, where he graduated as M.A. in 1875, and as M.B. in 1878. Entering the R.A.M.C. as surgeon on July 31st, 1880, he attained the rank of colonel on April 11th, 1908. As an administrative officer he served as principal medical officer, with local rank, in Mauritius in 1906–7, and, after his promotion, in South Africa in 1908–10, and in London up to his retirement on October 2nd, 1911. He served in the first Boer war in 1881, in the Bechuanaland campaign of 1885, and in the South African war in 1902, when he took part in operations in the Transvaal, the Orange River Colony, and Cape Colony, and received the Queen's medal with four clasps. He rejoined for service when the recent war began in 1914, and served as D.D.M.S. of the Western Command for the first month, as D.D.M.S. London Command for the three years, October, 1914, to October, 1917; as inspector of troops in the Eastern Command in 1917–19; and as A.D.M.S. at Bedford in 1918–19; being twice mentioned in dispatches, and receiving the C.B. in 1917. He was the author of *A List of Commissioned Medical Officers Serving in the Army from 1660 to 1727*. He married Miriam, daughter of the Rev. T. D. Kirkwood of Bridge of Allan. A former colleague (A. T.) writes: At the beginning of the war the D.D.M.S. London—that is, the senior army medical officer in the London District—was mobilized. He was replaced temporarily by the commandant of the R.A.M. College, who was succeeded by several senior army medical officers, all of whom broke down with the work. Colonel Peterkin, a retired officer, who had previously been P.M.O. London (an older name), then acting D.D.M.S. of the Western Command, was specially brought to London, and eventually put things straight. He was a particularly fine type of officer—sturdy, level-headed, and imperturbable. He had an uphill fight as, in addition to the ordinary army duties of his position, which in peace time were comparatively slight, he had to deal with five Territorial hospitals, many private hospitals run by ladies of title, etc., the Territorial units of the two London divisions, amounting to over sixty units, all of which, as well as the Guards and the Central Recruiting Depot at Whitehall, were recruiting briskly, and after a short while crowds of wounded arrived. Medical officers were very scarce, and the first addition to his staff was a retired non-medical major of the London Scottish, who was placed in charge of the transport of the wounded from the stations to the various hospitals.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on August 3rd the following medical degrees were conferred:

M.CH.—E. W. M. H. Phillips.
B.M.—J. W. de W. G. Thornton.

UNIVERSITY OF LONDON.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

THE following scholarships have been awarded for the session 1929-30:

St. Dunstan's Medical Exhibition: Miss M. I. McHaffie. Mrs. George M. Smith Scholarship: Miss B. Clark. Isabel Thorne Scholarship: Miss J. M. Cass. Dr. Margaret Todd Scholarship: Miss Q. I. May. Special Dr. Margaret Todd [illegible] Corner, Miss B. Wileman, Sarah [illegible] Miss D. Leachman, Miss M. A. Pov[illegible] ship: Miss J. M. Done. Ellen Walker Bursary: Miss M. E. Gould. Flora Murray Bursary: Miss O. N. Grant. Special Flora Murray Bursary: Miss P. Farncombe. Mabel Sharman Crawford Scholarship: Miss E. J. Browne. Helen Prideaux Scholarship: Miss M. Fraser. Dr. Edith Pechey Phipson Post-Graduate Scholarship: Miss N. R. Macadam.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on August 1st, when the President, Lord Moynihan, was in the chair.

Honorary Fellowship.

Dr. Aly Ibrahim, Dean of the Faculty of Medicine, Cairo, who was elected an honorary Fellow in November last, attended and signed the roll of honorary Fellows.

Research Scholarship.

On the recommendation of the Museum Committee it was decided to establish a research scholarship of £500 per annum, payable out of the general funds of the College, tenable from year to year for a period not exceeding seven years.

Diplomas and Licences.

Diplomas of membership were granted to 142 candidates. (The names were included in the list published in the report of the comitia of the Royal College of Physicians of London, printed in our issue of August 3rd (p. 227), as were also the names of those receiving the Diplomas in Public Health and in Ophthalmic Medicine and Surgery.)

Diplomas in Tropical Medicine and Hygiene were granted jointly with the Royal College of Physicians to the following:

[illegible]. Baboo, R. M. Buntine, [illegible]vasquez, G. H. Fitzgerald, [illegible]. K. Goh, S. A. Haque, [illegible]owther, D. D. McCarthy, [illegible]st, T. V. Rajagopalan, [illegible]. Salem, R. W. Scanlon, [illegible]. D. R. Thapar, H. A. Yenikomshian.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

West Ham Guardians.

IN the House of Commons, on July 23rd, Mr. CHAMBERLAIN moved a resolution for an address to the King, praying that certain orders made by the Ministry of Health in reference to the Bedwellty, Chester-le-Street, and West Ham Unions, in which appointed guardians are functioning, should be annulled. He said that the orders purported to extend the period of office of the present appointed guardians until August 2nd, but he understood that the Minister of Health intended to dismiss them on that date and, by a new order, substitute other appointed guardians, who would function until April 1st next. Since the appointed guardians had been at work all further borrowing by the unions concerned had ceased, and the financial position had improved. In addition, the West Ham appointed guardians had given a great deal of time and thought to improving the arrangements for the people to whose needs they were attending. At the hospital they had increased the efficiency of the medical and nursing service by appointing four consultants—a gynaecologist, an orthopaedic surgeon, an ophthalmic surgeon, and a neurologist. They had appointed a dentist and an anaesthetist, they had added one medical officer to the staff, and had substituted fourteen staff nurses for a corresponding number of probationers. In the children's homes they had provided a new and more varied diet at additional cost, and had changed the clothing of the children, which was heavy and unsuitable, for lighter and healthier clothing. They had encouraged games and outdoor exercises for the children, and had encouraged them to join the local groups of boy scouts and girl guides. In place of part-time district medical officers, full-time medical officers had been appointed, and the number of district nurses had been increased.

Mr. GREENWOOD, in reply, said that he had had to take some action as otherwise the orders affecting the appointment of the guardians in the three unions concerned would have come to an end on June 30th. He reappointed these gentlemen for the shortest possible time, and he proposed to go back to normality for all boards of guardians on April 1st of next year. His action was really in support of good administration, and would smooth the transition period before the Local Government Act came into operation.

The resolution was defeated by 284 votes to 154.

Conjunctivitis among Artificial Silk Workers.—Mr. CLYNES told Mr. Kelly, on July 25th, that the cases of conjunctivitis which had been the main source of trouble in the artificial silk manufacturing industry had been diminishing, and that, following on the conference which the chief inspector had last spring with the firms concerned, improved methods of ventilation were being tried which should result in a further reduction. The general health conditions continued to be satisfactory, but much remained to be done at some of the works to eliminate the eye trouble. He had asked the chief inspector to hold a further conference with the firms at an early date, to review the position and consider what further steps should be taken.

Undulant Fever caused by B. abortus.—In a reply to Mr. Guinness, on July 25th, Mr. NOEL BUXTON said he understood that the Ministry of Health would shortly issue a report containing the evidence, mainly obtained abroad, on which was based the theory that a form of undulant fever was caused by the bacillus which produced abortion in animals. The publication of this report would attract the attention of medical and veterinary practitioners and research workers to the study of this question, on which, so far as this country was concerned, there was at present little information.

Hospitals and Accidents due to Motor Traffic.—Mr. HERBERT MORRISON states that under Section 16 of the Local Government Act, 1929, hospitals maintained by local authorities may recover expenses for treatment of accidents due to motor traffic. He does not think it practicable to apply similar provisions to other hospitals or to impose an additional statutory charge on drivers' licences with a view to dividing the proceeds among them.

The Water Supply.—Answering questions on July 25th about [illegible] Mr. GREENWOOD said he was advised that there was no cause for alarm about the position of the water supply, but great difficulties in certain localities. No serious shortage of water in London was expected. Particulars of water supply were now being collected by local investigators. He was anxious that local authorities should undertake without delay measures on the lines advocated in a booklet issued by the Ministry of Health in October, 1928, which advocated comprehensive surveys through advisory regional committees.

International Labour Office Conventions.—Miss BONDFIELD stated, on July 24th, that as soon as necessary amendments had been made in the National Health Insurance Act as affecting Northern Ireland, the British Government would ratify the International Labour Office Conventions of 1927 concerning sickness insurance for agricultural workers, for workers in industry and mines, and for domestic servants. On the same date Mr. LAWSON stated that the Government intended to examine in the light of existing law and practice in this country, the League of Nations' Maternity Convention and other unratified International Labour Conventions. It was not possible to say yet what action would be decided on.

All-India Medical Council.—The Government of India recently convened a conference of representatives of provincial Governments to consider the proposal to create an All-India Medical Council. Mr. BENN had not, on July 25th, received a report of the conference. He hoped to be able shortly to make an announcement regarding the appointment of a Commissioner of Medical Qualifications and Standards.

Mental Examination of Convicted Persons.—Mr. LANG asked, on July 25th, whether, in view of the fact that for the three years 1926 to 1928 inclusive, 295 male and 43 female prisoners were certified as insane after their reception into prison as convicted persons, the Home Secretary would provide for the obligatory mental examination of all convicted persons before sentence. Mr. CLYNES replied that wherever there was reason for suspecting mental abnormality it was right that the court should have a medical report before proceeding to conviction and sentence. It was the duty of prison medical officers to make such reports on prisoners committed for trial or remanded by courts of summary jurisdiction to prison for medical observation.

Provision for Mental Defectives.—On July 25th Mr. GREENWOOD said his attention had been drawn to the cases of mental defectives in Plymouth who were in need of institutional care and for whom no vacancies could be found. The responsibility for making proper provision for mental defectives rested with the local authority, but the Board of Control [illegible] with regard to the provision of temporary [illegible] the provision of a colony jointly by the [illegible] and other local authorities. Any suitable proposal by the local authority would receive favourable consideration.

The Census of 1931 and Overcrowding.—In the House of Lords on July 24th Lord BALFOUR OF BURLEIGH asked the Government whether, in order to secure full information as to the existence [illegible] would be taken to distinguish, in the [illegible] houses of four and five rooms, and between [illegible] and for sleeping purposes. Lord ANSON, [illegible] that the whole question of the particulars [illegible] ensus of 1931 would receive the careful and earnest consideration of the Government at an early date, with a view to seeing how far changes should be made in them so as to enlarge the general information on the housing conditions of the people.

Notes in Brief.

The Secretary for the Colonies is obtaining the views of his advisory committees and of the Government of Northern Rhodesia on the provision of hospitals in the copperfields of that protectorate.

Answering the Duchess of Atholl, Mr. W. Adamson laid down that the after-care of children who, when at school, had been ascertained to have medical defects was not, in Scotland, a responsibility of education authorities.

A comparison is furnished by the Home Secretary of street accidents at points in London where roundabout and one-way traffic systems have been in operation for twelve months. This shows that from the inception of the systems, 16 persons have been killed at these points and 121 seriously injured, compared with 26 killed and 108 seriously injured in the corresponding period before the systems were introduced. Slight accidents were more numerous after the change.

Mr. Clynes states that arrangements are required to be made at every engineering factory for the first-aid treatment of eye injuries, but the subsequent provision of specialist treatment is outside the scope of the Factories Acts.

A draft report on the pollution of rivers will be ready for consideration in the autumn by the standing committee on that subject.

Of 138 male hospital officers in the prison service, 45 are registered by the General Nursing Council. Of 50 women hospital officers, 43 are fully trained nurses, all of whom are State registered. At Birmingham, Liverpool, Manchester, Parkhurst, Wandsworth, and Wormwood Scrubs prisons the principal hospital officer is not registered.

Mr. Greenwood states that the Registrar-General's estimates of population for the year 1928 were made with a greater thoroughness and with regard to a higher standard of precision than has hitherto been necessary, and effected some amendment of the intervening estimates.

During 1928 in England and Wales 161,412 cows were examined under the Tuberculosis Order of 1925, and 13,832 cows were slaughtered.

Mr. Buxton states that the International Veterinary Bureau, which exists to secure co-ordination of research into foot-and-mouth and other serious animal diseases, has recommended that Governments shall consider the exchange of specialists engaged in such research work.

Medical News.

The Minister of Health, the Rt. Hon. Arthur Greenwood, M.P., has appointed Mr. H. W. S. Francis, O.B.E., to be a principal assistant secretary, and Mr. R. H. H. Keenlyside, O.B.E., and Mr. J. N. Beckett to be assistant secretaries of the Ministry.

The Minister of Pensions has appointed a committee to inquire into the administration of the Queen Alexandra (Ministry of Pensions) Hospital, Cosham, Hampshire, and to report thereon. The members are as follows: Sir Frederick Willis (Chairman), Mr. John Bromley, M.P., Major J. B. Cohen, Mr. Isaac Foot, Sir Adair Hore, and Dr. Edward Mapother. It is understood that no public meeting of the committee will be held while legal proceedings arising out of the death of a patient at this hospital are pending.

The *Times* of August 1st contained the following information, described as an "official statement," which had been issued on July 31st: "A meeting of the National Radium Trust was held at the Privy Council Office to-day under the chairmanship of the Lord President of the Council, Lord Parmoor, at which the constitution of the Radium Commission and other matters connected with the Trust were considered. The meeting selected six names for membership of the Radium Commission out of the panel prepared by the medical authorities nominated in the Charter of the Trust. Steps were also discussed for ensuring that the Trust and Commission should be put on a business basis in order that as soon as possible benefit might be derived from the resources at the Trust's disposal. The appointment of a secretary and an assistant secretary will be announced shortly." We have received an intimation, dated August 1st, from the National Radium Trust, Ministry of Health, Whitehall, S.W., stating that the Trust has appointed Mr. P. Barter, of the Ministry of Health, to be its secretary, and Mr. Niven F. McNicoll, of the Department of Health for Scotland, to be assistant secretary.

A three months' course of lectures and demonstrations on clinical practice and in hospital administration will be given at the North-Eastern Hospital of the Metropolitan Asylums Board, St. Ann's Road, Tottenham, N.15, by the medical superintendent, Dr. F. H. Thomson, on Wednesdays and Fridays at 4.45 p.m., and alternate Saturdays at 11 a.m., beginning on October 2nd. The fee for the course, which complies with the revised regulations of the General Medical Council for the diploma in public health, is £4 4s. A course under the old regulations may be taken for £3 3s.

The Fellowship of Medicine announces that a fortnight's whole-day course in diseases of children will be given at the Queen's Hospital for Children from August 12th to 21st. Courses in September will be as follows: diseases of the chest, Brompton Hospital, September 9th to 14th; diseases of infants, Infants Hospital, September 9th to 21st; psychological medicine, the Bethlem Royal Hospital, Tuesday and Saturday mornings from September 10th to October 5th; medicine, surgery, and the specialties, the Westminster Hospital (for men graduates only) from September 16th to 28th. An experimental whole-day course in gastro-enterology will be arranged at the Prince of Wales's Hospital, Tottenham, from September 30th to October 4th; post-graduates interested in this course are asked to apply early for the syllabus. The Metropolitan Hospital, Kingsland Road, will hold an experimental course in medicine, surgery, and the specialties from October 21st to November 2nd; this course will occupy the whole of each day, and will cover all branches of medicine and surgery. Another evening course for the M.R.C.P. examination will be arranged from October 15th to December 6th; it will be held on Tuesday and Friday evenings at 8.30 p.m. at the lecture room of the Medical Society of London, 11, Chandos Street. Full particulars of all the courses are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

In view of the quality and number of the applications received for the two Chadwick Travelling Scholarships in Sanitary Science and Municipal Engineering, advertised in January last for award in July, the Trustees have decided to make three instead of two appointments. The successful candidates are Francis Bach, M.A., M.D.(Oxon.), to whom a scholarship is granted for the purpose of investigating the environmental and other causes of rheumatic diseases and their influence in producing diseases of the heart; Edmund A. Elsby, B.Sc., who is appointed to study and collect data in this country and America respecting the removal of silica dust from atmosphere in factories and other places where grinding operations are carried on; and John B. Dempster, B.Sc., to study sewage and sewerage with special regard to trade waste—alone and with crude sewage. All these scholarships are tenable for one year, and are of the value of £400 each.

In addition to the lists of medical practitioners serving as members of local authorities or their subsidiary bodies in Great Britain, which have been published in our columns from time to time, we have received intimation that Drs. G. H. R. Holden, William Hartnett, J.P., and D. Saunders Jones are members of the Reading County Borough Council.

The trustees of the William Shepherd estate have sent a third donation of £1,000 to the General Lying-In Hospital, York Road, Lambeth.

The seventeenth annual report on typhoid fever in the large cities of the United States, which has been recently issued by the *Journal of the American Medical Association*, deals with 81 cities in the United States with more than 100,000 population, and shows that nine cities had no typhoid deaths during 1928 (as compared with seven in 1927). Of the 45 cities with death rates below 2 per 100,000, 30 had the same low death rate in 1927. The six cities with populations of more than a million (Chicago, Cleveland, Detroit, Los Angeles, New York City, and Philadelphia) had rates below 2 per 100,000. The total typhoid death rate (627 deaths) for 74 cities in 1928 was a little lower than in 1927 (1.89 as against 1.96). The different groups of cities were in about the same order as in all the years since 1925 inclusive; the New England, East North Central, Middle Atlantic, West North Central, and Mountain cities all had low group rates very nearly alike, while the 1928 rates in the three Southern groups were far below the rates for 1925 and 1926 and, in the case of the East South Central, also far below the 1927 rate as well.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

Darwin's Home.

Dr. E. J. Pritchard (Wandsworth Common) writes: I was interested to read in the *British Medical Journal* of June 15th an account of the opening of Down House, "Charles Darwin's Home." Could you tell me where the house is? It might be a pleasant afternoon's motor run to visit it on some summer day, and I am sure there are many other medical men who would like to do likewise.

*** Down House stands a quarter of a mile from the village of Downe in Kent, at the edge of a narrow lane, some 16 miles from London Bridge, between the high roads to Westerham and Sevenoaks. In 1842, when Charles Darwin bought it and made it his home for life, a long coach drive was the only means of access. The nearest railway station now is Orpington (Southern Railway), four miles away; the village is not served by public conveyance. The accompanying sketch map may be of service to those who, like Dr. Pritchard, think of going to Down House by motor car.

TREATMENT OF FUNCTIONAL TACHYCARDIA.

"M.D.CANTAB." writes: "Puzzled" (July 27th, p. 171) should try *small doses of calcium lactate*. For nearly thirty years I had been subject to paroxysms of tachycardia and auricular fibrillation, often lasting eight hours and occasionally much longer. They often occurred without evident cause—for example, during sleep—and probably they were due to some chemical disturbance. I then found that calcium lactate (taken at first for chilblains) improved the general health and acted especially on the heart. I have taken 15 grains every night for seven years, and during that time have been almost entirely free from the trouble. I am 75 years old, and am still able to live a fairly active life.

INCOME TAX.

Resident Abroad Visiting the United Kingdom.

"INQUIRER" asks for information as to the circumstances in which a person working and residing abroad may become liable to United Kingdom income tax through visits to this country. He is unmarried, and has no residence in the United Kingdom.

*** The statutory rule is that a person is not chargeable to tax in respect of income received from abroad (1) if he is in the United Kingdom for some temporary purpose only and not with a view of establishing a residence, and (2) if he is also not actually in the country for six months in any one financial year. Both conditions must be complied with to entitle the visitor to exemption. *The difficulty in the application of the rule lies in* the interpretation of the first of the two conditions. On that point the Board of Inland Revenue issued a public memorandum some months ago, a copy of which would, no doubt, be forwarded to "Inquirer" on application to the Secretary, Inland Revenue, Somerset House, London, W.C.2. Briefly stated, the view of that department—based apparently on judicial decisions of the High Court in recent years—is that even though a visitor does not maintain a place of abode in this country, and does not stay for six months in any one year, he becomes a resident if he visits this country habitually year after year and the annual visits are for substantial periods. The memorandum went on to say that normally the department would regard visits of three months as "substantial" and visits as becoming "habitual" after four years, and further, that where the visitor's arrangements indicated from the start that regular visits for substantial periods were to be made he would be regarded as resident in and from the first year. *Unless and until that statement of the legal* position is successfully challenged in the High Court it may be taken as authoritative. If liable at all on his foreign income, "Inquirer" would be taxable only on that part of it which he received in or had remitted to the United Kingdom, and he would be entitled to the usual personal reliefs—£135 free, £225 at half rate, etc.

Partnership Agreement.

"S. A. M." took a partner into his practice "on July 1st, 1928, and paid him a salary till July, 1929 (not in agreement)." The local official requests the production of the partnership deed. Is he *entitled to demand its production?*

*** The assessor or inspector has no specific powers under the Income Tax Acts, but the Commissioners responsible for dealing with the assessment could refuse to grant the personal allowances against the gross assessment until they have been satisfied as to the correct method of dividing the burden between the partners. The local official is probably making his request with a view to arriving at an agreed basis of division; in the absence of that agreement the Commissioners will, no doubt, use their statutory powers. On the merits of the particular case the request is the more difficult to refuse, as the payment actually made seems to have been different from that for which the agreement provided. Section 20 of the Income Tax Acts, 1918, lays down the rule that "the income of a partner . . . shall be deemed to be the share to which he is entitled during the year to which the claim relates," and the exact provisions of the partnership agreement are therefore material.

LETTERS, NOTES, ETC.

SIR JAMES BARRIE AND LANDLADIES.

SIR JAMES BARRIE'S speech on the occasion of the conferment upon him, on July 29th, of the freedom of the city of Edinburgh has been very fully reported in the public press, but it is perhaps justifiable to repeat his delightful tribute to his old landlady, and to good landladies in general, in a medical publication, for generations of medical students, especially in Scottish universities, where the system of residential halls has never been greatly in evidence, have had good reason to be grateful to their landladies. Sir James's remarks, therefore, must have struck a responsive chord in the memory of many who were students at Scottish universities. He said: ". . . Without throwing discretion to the winds, I shall tell you about the woman. I would rather have had her here to-day than almost anyone I can think of. If she had been here, I am sure she would have been wearing a black silk dress, or something she considered uncommonly like it. She kept lodgings—fortunately for me. She was an old and poor widow woman, without kith or kin, but I think it would ill become me to stand up in Edinburgh without recalling the fragrant memories of Mrs. Edwards. In after-years, when I used to go and see her, she would shake a playful fist at me and say: 'Yer play wis here, being acted by the play-actors, and I wis fain to go, but, oh, Mr. Barrie, I coulina daur!' If she had lived into the war I can conceive her forcing her way on to the Castle to fire Mons Meg at the enemy. I can hear her, pausing after each shot to shout out: 'Count your men now, Mr. Kaiser!' A short play of mine, *The Old Lady Shows Her Medals*, was written entirely thinking of Mrs. Edwards. Why is it that landladies are so much maligned? I think all we old Edinburgh graduates, who had good ones, might do worse than raise a statue in Edinburgh to the students' friend."

PROFESSOR HILL'S POPULAR LECTURE.

DR. AGNES ESTCOURT-OSWALD (Colchester), in the course of a letter with this heading, writes: From the report in the *British Medical Journal* of the Popular Lecture given at Manchester, *Professor A. V. Hill seems to have wished to impress upon his* audience that the various advances in modern medicine and surgery depended upon experiments on animals. The question that one naturally asks is, "Does such dependence really exist?" A fact having been found out in one way, it would be absurd to say it could be found in no other. Because America was discovered by a sailing vessel should not make anyone declare that the discovery of America depended on such primitive craft, and that a steamer could not have done the job. During the last hundred years or so many benefits—the greatest, I believe—have accrued to mankind from the science of medicine without experiments on animals. Therefore there is no reason to think that no more benefits will arise except by the infliction of suffering on living creatures. And it is the suffering of animals to which the antivivisectors wish to put an end; not, as Professor Hill said, "to all this research." No one wants to end any research which can be guaranteed to cause no suffering to any animal except for its own individual benefit.

MILK AND COMMUNICABLE DISEASE.

MR. P. B. TUSTIN (United Dairies Ltd.) writes: It is *disconcerting to hear of a medical man of the prominence of Dr. Charles* McNeil making the fantastic and misleading statement (at the Annual Meeting of the British Medical Association) that tuberculous milk, which constitutes the greatest and most serious example of food poisoning, is widespread in this country. Great Britain may not lead the way among the countries of the world in regard to the quantity of milk consumed by its population, but it is generally agreed to be in the front as far as purity of supply is concerned. At the Public Health Conference organized by the Ministry of Health at the Agricultural Hall last year, and again at the Royal Sanitary Institute Conference at Sheffield this year, I asked a large number of medical and sanitary authorities if anyone present could tell me of an outbreak of communicable disease caused by milk that had come under his own personal knowledge during the past ten years. In neither case was a reply given in the affirmative. In the United States official report for 1926–27 all the outbreaks of disease were due entirely to raw milk; 104 *epidemics were* definitely traced to milk. The reason of our freedom from outbreaks is that milk in London and other large centres is nearly all pasteurized.

ASSOCIATION OF RICKETS WITH A CYSTIC KIDNEY.

DR. S. F. LEAVINE (Kitchener, Ontario) suggests that renal disease may possibly be concerned in some forms of rickets. He reports a case in a boy, aged 5, who began to limp and suffered from pain in the knee and left hip, which became progressively worse. This was associated with an abdominal tumour, apparently of renal origin. Although an *x*-ray examination suggested a tuberculous etiology for the hip condition, the Pirquet and [illegible] were *negative*, and the *blood only* lymphocytosis, which was considered [illegible]ge; the urine showed no abnormalities [illegible] cystic kidney was removed, and after two months treatment by cod-liver oil and *sunshine* the patient recovered perfectly, though a radiological examination subsequently revealed irregular destruction and condensation in the neck of the femur, suggesting chronic osteomyelitis. While Dr. Leavine admits the possibility of coincidence in this case, he suggests that the condition may have been rickets of renal origin.

THE CERVIX DURING COITUS.

DR. MAURICE B. JAY (Clapton Common, E.5) writes: The following case is interesting, as it seems to throw light on the action of the cervix uteri during coitus. I was called to see a woman who informed me that one hour previously, during coitus, a part of the sheath worn by her husband was torn away and remained in the vagina, whence she could not remove it. On examination I found the sheath firmly fixed in the cervical canal; some force was required to pull it out. As about 2 in. of the sheath was in the canal, I think the tip must have passed through the internal os. I examined the woman the *following day*; the cervix was quite healthy, and the cervical canal would not permit the passage of a fine probe.

VACANCIES.

NOTIFICATIONS of offices vacant *in universities, medical colleges*, and of vacant resident and other appointments at hospitals, will be found at pages 37, 38, 39, 42, 43, and 44 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *116*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

98. Herpetic Fever.

H. PETTE (*Acta Med. Scand.*, May 28th, 1929, p. 421), who records an illustrative case, states that herpetic fever was first described as a clinical entity by Griesinger. The lively discussion which ensued showed that by no means all the cases of transient fever followed by more or less extensive herpes simplex were of herpetic origin. Kühn in particular pointed out that many cases of so-called herpetic fever were really examples of rudimentary pneumonia with a herpetic eruption. Subsequently Schottmüller showed that many cases of one-day fever with herpes simplex were the result of an acute *B. coli* infection of the urinary tract. At present, however, Pette has no doubt that febrile states with extensive herpetic eruption do exist; they cannot be regarded as the expression of pneumonia or any other infection, but are probably entirely due to the virus of herpes. Zlocisti in 1920 described a number of cases which he saw in Constantinople and regarded as examples of herpetic fever, as he was able to exclude every other infection by careful bacteriological and serological examination. The cases occurred in men, aged from 20 to 40, who became ill with symptoms of shivering and fever and developed extensive facial herpes, usually on the third day as the temperature fell. Lauder and Luger, after careful study of the literature, also came to the conclusion that there was a clinical entity which, owing to its most prominent symptoms, could rightly be described as herpetic fever. Pette's patient was a man, aged 31, who within the last six years had repeatedly suffered from attacks resembling influenza, followed by acute meningitis with very extensive facial herpes; he always recovered in a few days. Experimental evidence was found of the presence of a very virulent strain of herpes which caused the herpes facialis, though the virus was not detected in the cerebro-spinal fluid or blood.

99. Cerebral Complications in Broncho-pulmonary Cases.

A. GORDON (*Med. Journ. and Record*, June 19th, 1929, p. 694) states that complicating cerebral manifestations may occur in broncho-pulmonary affections of prolonged duration, though the lung disorder may be so pronounced that the brain symptoms may be overlooked. In a case which he reports bronchiectasis was associated with abscesses in the right temporal and left frontal lobes and in the posterior horn of the left lateral ventricle. The pus from these revealed the presence of non-haemolytic streptococci. The patient had suffered from bronchitis for several years and from severe headache for many months, but, owing to the absence of gross objective motor and sensory phenomena, the nervous complications were overlooked. Brain abscess has been observed in many broncho-pulmonary conditions, and among these the most common is bronchiectasis, probably due to its longer duration. Then follow in order of frequency lung suppuration, tuberculosis, empyema, and pneumonia. The formation of these abscesses may be due to thrombophlebitis, metastasis, or to direct bacterial invasion through the small pulmonary or bronchial veins to the superior vena cava, the jugulars, the cerebral sinuses, and finally to individual veins in the brain. Gordon emphasizes the point that the absence of gross symptoms of an organic involvement of the central nervous system does not always exclude invasion of brain tissue, and that, when the motor or sensory cortex or other important cerebral centres are not involved, the respective clinical signs will be absent. Persistent severe headache with periodic attacks of somnolence indicate cerebral involvement, and attention should be directed to areas other than the special centres of the brain. According to Eagleton, the frontal lobe is the most frequent seat of abscess. The temporal lobe, especially its apex, is another site involvement of which may be unaccompanied by any marked signs.

100. Spinal Changes in Pernicious Anaemia.

B. M. FRIED (*Journ. Amer. Med. Assoc.*, April 13th, 1929, p. 1260) discusses the histological changes which occur in the spinal cord in the course of pernicious anaemia, and comments on the limitations of liver diet. He shows that whereas the degenerative cellular changes in the visceral organs in this disease are often followed by restitution of structure and function, analogous processes of regeneration of nerve cells or fibres in the central nervous system have never been observed. In pernicious anaemia the nerve cells and axis cylinders of the white matter of the cord become degenerated, and are eventually replaced by fibrous tissue. Advanced sclerotic changes, however, are seen relatively seldom, possibly because the process of organization in pernicious anaemia is extremely slow. The histological picture is essentially that of a progressive degeneration and not of inflammation. Liver diet does not cure pernicious anaemia, but leads to a protracted remission, during which the lesions of the central nervous system probably do not progress. Before this treatment was introduced natural remissions of the disease occurred, but during them the spinal lesions remained, as a rule, active and even became more marked. It is not to be expected, therefore, that great improvement in the nervous symptoms of pernicious anaemia will follow the continued administration of liver, and the author adds that it is remarkable that some functional improvement does, nevertheless, occur.

101. Typhoid Infection of the Spine.

A. DOUBLET (*Thèse de Paris*, 1929, *No.* 96), who records six cases in persons aged from 10 to 42, one of which is original, states that typhoid spondylitis is a relatively rare localization of typhoid bacilli. It usually occurs in adults, but adolescents and even children are not immune; it most frequently appears at the onset of convalescence. The principal symptoms are sudden and severe lumbar pain, most marked at night. The bone and joint lesions are characterized by disappearance of the intervertebral discs and the production of osteophytes. Sensory or sphincter troubles are absent, and the constitutional disturbance is slight. The Widal reaction is always positive for *B. typhosus* or *B. paratyphosus*. The condition must be distinguished from acute vertebral osteomyelitis, high sciatica, and especially incipient Pott's disease. The diagnosis is made by the history, symptoms, and Widal test. The condition is of relatively long duration, as it may last from two to six months. But whereas all the other forms of typhoid osteitis end in suppuration, it is rare to find abscesses in typhoid spondylitis. The prognosis is good as regards life, and under modern treatment is also favourable as regards recovery of function. Treatment consists chiefly in rest in the horizontal position, with slight immobilization if necessary. It is most important, however, to inject typhoid or paratyphoid vaccine, or both, as early as possible.

102. Etiology of Influenza.

K. KISSKALT (*Deut. med. Woch.*, April 19th, 1929, p. 648) deprecates regarding the bacillus in influenza as the most important factor in etiology. He remarks that the most striking phenomenon in connexion with influenza is its seasonal occurrence. It is hardly ever possible to foretell the occurrence of other epidemic diseases, but expectation of the appearance of influenza from the close of the year until April is very often realized; prophylaxis should therefore be undertaken accordingly. Influenza is stated by Kisskalt to be a disease which is more frequently caused by damp shoes than by cold air; changing wet shoes and stockings is therefore a wiser plan than attempting to avoid an often inevitable infection. He adds that, as regards the morphology and biology of the casual agent, the objection to Pfeiffer's bacillus being so considered is that it has not been found at the beginning of pandemics even by expert investigators. Its subsequent wide dissemination may be explained by an epidemic spread of a saprophyte, as Kisskalt claims to have shown to occur in the case of *Streptococcus pleomorphus*.

103. Sex Factors in Influenza.

E. APERT (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, May 20th, 1929, p. 625) presents figures showing that during the epidemic of influenza in 1918 the attacks were accompanied by a higher temperature, had a longer duration, and were more frequently complicated and fatal in girls than in boys. The deaths from pneumonia and other respiratory diseases, with the exception of tuberculosis, not only in childhood but also in adult life, were also than in males during that period. In epidemic of the first quarter of 1929 t were more than a quarter heavier among females than among males, while as regards the diseases of the respiratory tract most liable to be affected by influenza, such as pneumonia and bronchitis, the mortality was only three times the usual rate in the male sex, whereas it was more than five times the

normal in the female sex. The greater susceptibility of the female sex to the virus of influenza was thus confirmed in the recent epidemic. Apert had previously shown that the same was true as regards whooping-cough.

104. Clinical Significance of Premature Heart Beats.

J. W. ESLER and P. D. WHITE (*Arch. Int. Med.*, May, 1929, p. 606) compare a series of 100 patients with premature heart beats but no marked degree of auriculo-ventricular or intra-ventricular block with 100 patients whose cardiac rhythm was normal, their object being to determine the prognostic significance of this condition with special relation to the degree of cardiac rapidity. They found that the prognosis was no graver when premature beats were associated with a rapidly beating heart, when due allowance was made for the increase in mortality attributable to the increased rate alone. Auricular premature beats were not found to be more significant as regards prognosis of life than were the ventricular beats; in the latter the prognosis was not more serious when the origin was multifocal, and the authors doubt whether such multifocal premature beats are always accompanied by myocardial involvement. The frequency with which premature beats occurred in a given case seemed to bear little relation to prognosis.

105. Musculo-tendinous Contracture in Syphilis.

M. FAVRE (*Journ. de Méd. de Lyon*, May 20th, 1929, p. 347) describes a peculiar condition known as syphilitic contracture of the biceps, which sometimes begins suddenly, causing limitation of extension of the forearm; any attempt at extension is painful, and the biceps is abnormally tender at the junction of the tendon with the muscle fibres. This syphilitic contracture occurs most frequently during the secondary period, but it may be found much later. It appears to be peculiar to syphilis, and Fournier asserted that it had never been found definitely in any muscle other than the biceps. Favre, however, describes the case of a man, aged 31, in whom the gastrocnemii were involved. He had severe pain on walking or standing. The condition had been diagnosed as rheumatic, but he had a large whitish scar on the prepuce. The ulcer had been thought to be a soft chancre, and the patient had not received any antisyphilitic treatment. His Wassermann reaction was strongly positive before the commencement of treatment. The pain in both calves forced the patient to maintain full extension of his feet; these pains had persisted for fifteen days, and had been preceded by nocturnal headache, lumbar pain, general weakness, and slight fever. Immediate improvement followed antisyphilitic treatment, and the patient was quite freed from pain in six weeks after commencement of treatment.

106. Prognostic Value of Intradermal Injections of Horse Serum.

A. FIORENTINI (*Il Policlinico*, Sez. Prat., May 27th, 1929, p. 731) gives the results of some 700 injections of horse serum in 223 patients suffering from various diseases, mostly tuberculosis or syphilis. He finds that a negative reaction is of bad prognostic import, especially when this is persistently negative or becomes negative after a brief positive reaction. Of the 46 who gave a persistent negative reaction, 7 died. The patients could be classified in three groups: those who gave a positive reaction at once; those who gave a preliminary negative followed by a positive reaction; and those who were negative throughout. In the third class the prognosis is unfavourable.

107. The Healthy Carrier in Scarlet Fever.

R. TUNNICLIFF and T. T. CROOKS (*Journ. Amer. Med. Assoc.*, May 4th, 1929, p. 1498) record an outbreak of fourteen cases of scarlet fever which was traced to three healthy carriers of scarlet fever streptococci. The method of detection is as follows. Cultures are taken on the ordinary Loeffler's medium for diphtheria bacilli. This is sent to a laboratory, where blood-agar plates are made. If after eighteen to twenty-four hours' incubation haemolytic streptococci are not present, it is assumed that the culture is negative for scarlet fever. If haemolytic streptococci are present, they are examined by the following rapid opsonic method. Equal parts of normal human serum, citrated blood, and bacterial suspension are mixed in bent capillary pipettes, and the mixtures are incubated for twenty-five minutes at 36°C. They are then smeared on glass slides and stained; fifty or more polymorphonuclear leucocytes are counted, and the number of cells taking part in phagocytosis is noted (phagocytic index). If the phagocytic index of the immune serum exceeds that of normal serum determined by the same method, it is concluded that the coccus belongs to the scarlet fever group. The opsonic indices with the scarlatinal streptococci from the carriers in the authors' series varied from 4 to 18.

108. Nephritis in Diphtheria.

J. BÉDOURET (*Thèse de Paris*, 1929, No. 68), who records seven illustrative cases in patients aged from 2 to 38 years, states that two clinical forms of diphtherial intoxication of the kidney may be encountered. The first is a temporary albuminuria which has no prognostic significance, while the second is a nephritis which is much more serious. Bédouret maintains that the diphtheria toxin, apart from association with other organisms, and especially streptococci, is not capable of giving rise to this nephritis. Pathologically the condition is a tubulo-nephritis without glomerulitis. The existence of the nephritis is not a contraindication to serum treatment.

Surgery.

109. Transillumination in Breast Lesions.

M. CUTLER (*Surg., Gynecol. and Obstet.*, June, 1929, p. 721) calls attention to the value of transillumination as an aid to the diagnosis of breast lesions, and especially to their localization in cases of bleeding nipple. The examination is made in a totally dark room with a Cameron transilluminating electric light placed against the under surface of the breast and gradually moved for the inspection of different areas, so that any particular portion is directly between the light and the examiner's eye. The degree of translucence can be increased by compressing the breast between the hand above and the light beneath. The findings vary normally, depending mainly upon the relative content of fat, fibrous tissue, and epithelial elements. The study of 174 pathological breast conditions showed the value of the method as an aid to differential diagnosis and treatment, it being found that acute, subacute, and chronic inflammations present a diffuse opacity, which diminishes and disappears as the inflammation subsides. Solid tumours are opaque, the degree of opacity varying with their size and location, but without affording a means of differentiation between benign and malignant tumours. Cysts containing clear fluid are translucent, and this may be of great value in differentiating carcinoma from tense deep cysts with skin adherence clinically simulating a malignant growth. Blood effusions are intensely opaque, and a traumatic haematoma shows an irregular outline disappearing as the blood is absorbed. The method is of especial value in cases of bleeding nipple in which no tumour can be palpated, and it affords a means of distinguishing between those due to a single localized papilloma and those caused by multiple papillomata, its practical importance being demonstrated by those cases in which the removal of a duct papilloma has failed to cure, while on subsequent transillumination several opacities point to the existence of multiple lesions. When, however, the discharge from the nipple is not distinctly haemorrhagic, localization may be impossible.

110. Sarcoma of the Prostate.

H. E. PAUL (*Urol. and Cutan. Review*, May, 1929, p. 307), who records a fatal case in a boy aged 14, states that sarcoma of the prostate is a rare disease, as only about 85 cases have been reported in the literature. Parmenter in 1917 collected 59 cases, to which Culver added 17 more in 1925, including one of his own; in 1926 Kretschmer reported 2 more from his own practice. About one-third of the cases occurred in patients under the age of 10, though the ages in all reported cases range from 8 months to 77 years. Perineal injury prior to the onset has been frequently reported, but probably the trauma only hastens the progress of the growth. Metastasis is usually by the blood stream, especially in the young. Eleven pathological types of sarcoma have been described, the following six being the commonest in order of frequency: round cell, spindle cell, myxosarcoma, lymphosarcoma, rhabdosarcoma, and angiosarcoma. The symptoms are those of vesical and rectal obstruction. In adults, in whom the progress is less rapid than in children, intestinal disturbance, such as constipation alternating with diarrhoea, is common. Haematuria is not frequent.

111. Post-operative Meningococcal Infection.

M. PERRIN, V. DE LAVERGNE, and M. POIRIER (*Paris Méd.*, May 11th, 1929, p. 465) record the case of a soldier, aged 21, who, four days after spinal anaesthesia for radical cure of inguinal hernia, developed a meningococcal infection which at first assumed a septicaemic form of the pseudo-malarial type, with which a meningeal form was subsequently associated. The discovery of the meningococcus in the cerebro-spinal fluid confirmed the clinical diagnosis of meningococcal infection. The disease was unusually protracted, as it lasted for nine months, and was not benefited by any treatment, including serotherapy, protein therapy, and two fixation abscesses. Although it is possible that the trauma caused

by the spinal anaesthesia had nothing to do with the development of the infection, the authors think it more probable that there was a relation of cause and effect. It is very likely that the spinal anaesthesia, whether by removal of fluid or by the addition of foreign material, caused a considerable change in the composition and tension of the cerebro-spinal fluid. Consequently, the organs concerned with keeping the composition and tension of the cerebro-spinal fluid constant, particularly the choroid plexuses, showed an increase of function. As the result of absorption the lymphatics draining the nasopharynx, in which the meningococcus was present, came in contact with the cerebro-spinal fluid, and thus the infection became generalized.

112. Primary Neoplasms of the Renal Pelvis.

L. HERMAN and L. B. GREENE (*Annals of Surgery*, May, 1929, p. 682) point out that carcinomata comprise approximately 5 per cent. of all renal neoplasms, and consider that the majority of extensive new growths of epithelial origin originate from the pelvic mucosa. Infiltrating, non-papillary, or alveolar carcinomata are always malignant, and, in spite of microscopic characteristics of benignancy, it may be assumed that all papillary tumours are inherently malignant. Primary non-papillary neoplasms of the renal pelvis originate from the transitional epithelium; the parent cells are probably certain ones which have become squamous in type as the result of metaplasia, or true ectodermic cells representative of developmental inclusions. Chronic irritation is an important predetermining factor in squamous-cell epithelioma of the renal pelvis, and a chronic bacterial inflammation, calculus, or leucoplakia is usually present. The type of tumour generally associated with calculi is characterized by early replacement of the renal parenchyma by tumour cells and fibrosis, leading to enlargement, induration, nodulation, and dense fixation of the kidney. Metastasis by way of the lymphatics occurs very early in the course of squamous-cell tumours of the renal pelvis. Perirenal nerve involvement and carcinomatous infiltration of the parenchyma usually denote inoperability. The prognosis is very bad, and out of a series of 30 patients operated on 16 died as the result of operation; the average length of life among the survivors was only seven and a half months. It would appear to be impossible to recognize the condition as neoplastic early enough to permit complete eradication of the disease by nephrectomy. Papillary tumours are less malignant, but give rise in 70 per cent. of cases to tumour implants in the ureter and bladder. In most instances parenchymal invasion and metastatic dissemination occur comparatively late in the disease. Haematuria, often massive and sometimes painless, is present in 90 per cent. of cases, and generally appears comparatively early. Renal colic, caused by the passage of clots or by pelvic blockage due to a pedunculated growth, is a frequent symptom. Palpable renal enlargement, when due to parenchymal involvement, indicates inoperability. In the majority of cases the diagnosis of intrapelvic tumours can be made certain by means of pyelography. Treatment should be surgical whenever possible, followed by the exhibition of radium.

113. *Treatment of Furunculosis.*

W. MAYER (*Münch. med. Woch.*, May 17th, 1929, p. 838) points out that the treatment of superficial boils by the method of complete rest and poulticing is often impracticable under industrial conditions. He therefore advocates the following procedure, which has also been found useful in factories and hospitals. If a furuncle requires opening a piece of aluminium foil, perforated by a hole 4 mm. in diameter, is placed on the affected skin so that the furuncle projects through the hole and can be readily frozen by ethyl chloride; a small incision is made and any escaping pus wiped away. The lesion is then dressed with an ointment cell dressing. This consists of a strip of rubber adhesive plaster in which a circular hole has been cut, covered with cellophane tissue, and surrounded by a ring of felt; these together form a small cell which is filled about three-quarters full with an ointment containing pure phenol, camphor, and ichthyol. Since the phenol is analgesic and the camphor induces hyperaemia the dressing has a soothing effect, while the ring of felt not only keeps the ointment in contact with the lesion longer than if it were spread on gauze, but also protects the surrounding skin follicles from infection. The core of the boil is extruded in a few days and healing is more rapid than with moist dressings. Other advantages of this dressing are said to be that it remains in position, even on the limbs, and does not require adjusting; it is impervious to water, so that the patient can wash as usual. Both the disc of plaster and the cellophane window can be removed by sponging with ether if it is necessary to re-dress the lesion; a fresh application of ointment is then introduced and covered with another disc of cellophane. Occasionally a fresh dressing has to be applied after a few days, but in many cases one was found to be sufficient. The antiseptic action of the ointment was demonstrated by applying the dressing to the surface of an agar plate inoculated with cultures of staphylococci and streptococci, and incubating. No growth occurred in the area in contact with the ointment, though numerous colonies appeared on the rest of the plate.

114. Post-operative Thrombosis and Embolism.

ACCORDING to E. SULGER and T. BOZSIN (*Deut. Zeit. f. Chir.*, May, 1929, p. 175) there has been in recent years a considerable increase in the number of fatal cases of pulmonary embolism following operations. Several causes have been suggested, such as intravenous therapy, infections (especially influenza), therapeutic use of metals (such as mercury, silver, and arsenic), changes in diet, and potassium nitrate. In the Heidelberg surgical clinic there were 24 fatal cases of pulmonary embolism in 1926, 18 in 1927, and 16 in 1928. During the last two years the authors have been treating thrombosis of the leg by the application of leeches, of which four are usually placed over the affected vein. The subsequent bleeding is considerable, and the patient experiences great relief. Infection of the bites very rarely occurred. At Kleinschmidt's suggestion they have recently been using leeches as a prophylactic measure against post-operative emboli, but their observations are not at present sufficiently numerous to justify any conclusions. No bad effects have resulted from the method.

115. Surgical Treatment of Gastric Cancer.

FINSTERER (*Zentralbl. f. Chir.*, May 25th, 1929, p. 1306) gives the following statistics of 535 operations performed for carcinoma of the stomach; 340 were resections, 8 total extirpations, 88 gastro-enterostomies, and 99 exploratory laparotomies or jejunotomies. The results were relatively satisfactory when the stomach alone was resected, there being 13 deaths, or a mortality of 6.1 per cent., among 211 simple gastric resections. In 129 complicated resections in which the pancreas, colon, or oesophageal wall was involved, the mortality was as high as 41 per cent. In advanced age (60–78) the results were not decidedly worse than in younger patients, the mortality being 5.7 per cent. among 139 cases under 60, as compared with a mortality of 6.9 per cent. among 72 cases over 60. In 85 complicated cases under 60 the mortality was 42.3 per cent., as compared with a mortality of 38.6 per cent. in 44 cases over 60. The remote results were as follows: 50 out of 199 cases resected, or 25 per cent., had been free from recurrence for periods ranging from five to eighteen years; 14, or 17 per cent., of those kept under observation for ten years had been free from recurrence. In the case of carcinoma following gastric ulcer the remote results were worse than with primary carcinoma, for although 10 out of 32 incipient cases had remained free from recurrence for longer than five years, only one out of 28 advanced cases had shown no recurrence at the end of five years.

Therapeutics.

116. The Treatment of Gout.

P. F. RICHTER (*Deut. med. Woch.*, May 17th, 1929, p. 821) considers the therapy of gout under three heads: (1) the *acute attack*; (2) the *period free from attacks*; and (3) chronic gout and its results. In the acute attack colchicum and atophan are the two certain drugs. Colchicum (Merck) in doses of 1 mg. is administered five to six times within two hours; and if the pain has not *quite disappeared on the* following day two or three tablets are given during the twenty-four hours, but continuing it further is not advisable. The prophylactic action of colchicum is quite uncertain. Richter warns against the many proprietary preparations which contain colchicum in insignificant quantities, and also against tinctura colchici or vinum colchici in which the colchicum content is not standardized. The way in which colchicum acts is, he adds, still unexplained. The relief from pain by colchicum is in most cases dramatic, but it is often associated with unpleasant weakening of the patient and more or less severe diarrhoea, although according to some authors it is this purging effect which has so much benefit on the acute attacks. Atophan and novatophan act more slowly than colchicum and less surely in acute attacks, but they can be given for a longer period, and produce no important secondary effects. On the first day 2 to 6 grams are given, and on subsequent days half that dose until the pain and swelling have gone; by the intravenous injection of atophan or of atophan with salicylic acid (atophanyl) a more rapid effect is obtained than by oral administration. Diet in acute gout should be mild and non-stimulating, but a strict purin-free diet is not advocated. The treatment of gout during the periods free from acute

attacks is chiefly dietetic; foods with high purin content, such as liver, kidney, brain, pigeon, certain fish, beans, lentils, and mushrooms, should be avoided. The alkali and acid therapy is often useful from its beneficial effect on the stomach and bowels; treatment at spas with the idea of removing surplus uric acid from the tissues of the kidneys is of doubtful use. The action on chronic gout of massage and baths is still but little understood, though clinically it is of undoubted value.

117. Digitalization by a Small Dose Method.

H. GOLD and A. C. DEGRAFF (*Journ. Amer. Med. Assoc.*, April 27th, 1929, p. 1421) remark that it should be remembered when considering whether digitalis should be prescribed that while this drug in cases of failing circulation sometimes brings about striking improvement, there are, nevertheless, types of failing circulation in which its use is indicated on the basis of certain experimental data and theoretical considerations, but clinically little, if any, beneficial effect results. Numerous errors in the interpretation of clinical observations have arisen from failure to consider this distinction. There is no essential difference between the behaviour of digitalis in children and adults. The drug less often produces striking improvement in children because the type of heart failure that is relieved most effectively by digitalis (congestive heart failure without active infection of the heart) is relatively common among adults and rare among children. In those cases in which less definite therapeutic effects are obtained, insufficient or excessive digitalization is more apt to occur because of the absence of a satisfactory guide to the intensity of digitalis action. The gradual accumulation of digitalis in the body which occurs in the course of daily administrations of a suitable fixed dose of the drug can be shown to be a self-limiting process; the intensity of therapeutic action present at the time when further accumulation ceases depends on the size of the daily dose. Experiments are cited which show that, contrary to the view commonly held, a patient does not eliminate a fixed quantity (2 grains of digitalis leaf) of digitalis daily, but a quantity which varies with the amount present in the body; the full therapeutic effects of digitalis may be induced in many cases by the daily repetition of such doses as the patient may eliminate daily after having been fully digitalized. Prescribing the drug on these lines diminishes the danger of toxic symptoms being evoked.

118. Indications for Salt Treatment in Bright's Disease.

L. BLUM, VAN CAULAERT, and GRABAR (*Presse Méd.*, May 1st, 1929, p. 569) divide cases of nephritis into two types: (1) with oedema (always associated with excess of chloride in the organism), and (2) dry nephritis, which may be found with a normal, increased, or diminished amount of chloride. The diagnosis of hypo- and hyper-chlorhydria is considered at some length in terms of the chloride contents of the serum or plasma, of the total blood, of the cerebro-spinal fluid, and the chloropexic index of the red cells. These considerations are then applied to the different types of nephritis. Clinical diagnosis is sometimes difficult without laboratory means. The authors state that after a diagnosis of hyperchlorhydria or hypochlorhydria has been reached treatment becomes simple, and they give the following three practical rules. (1) Every nephritis case with oedema demands a strict non-chloride regime. (2) Dry and non-azotaemic nephritis requires no salt; if laboratory investigation is not available it is better to suppress or limit salt in every case. (3) In dry azotaemic nephritis it is difficult to tell whether there is chloropexy or chloropenia, and the aid of the laboratory must be sought. In hypochlorhydria salt must be given boldly in quantities sufficient to replenish the chloride insufficiency in the body. Repeated intravenous injections are advised in urgent cases, but subcutaneous injections are advocated as the method of choice in cases of less urgency. Salt can also be given by the mouth, but in patients subject to vomiting or to diarrhoea this method may be rendered useless. The authors emphasize the advice that water is as indispensable as salt; the administration of intravenous injections of hypertonic solutions can only be of temporary therapeutic value, and should be replaced by injections of dilute solutions.

119. Synthalin in Diabetes.

ELAINE P. RALLI and CONNIE M. GUION (*Journ. Lab. and Clin. Med.*, May, 1929, p. 699) consider that experimental and clinical results of different investigators indicate that synthalin causes a reduction of blood sugar in both normal and diabetic subjects; various hypotheses have been advanced as to its mode of action and effect on liver function. Synthalin is a derivative of amino-penthylen-guanidin, in which, by lengthening the methyl chain, the toxicity of the basic group is greatly lessened; it has been asserted that its oral administration will lower the blood sugar in diabetics. Twelve cases, with the doses employed in each, are here reported, all of which showed a definite fall in blood sugar. The urine in each case remained sugar-free, and urobilinogen tests were negative in all but one, in which they were only faintly positive. These patients showed no loss of weight, and when the synthalin was stopped the blood sugar rose and glycosuria reappeared. Only one case showed any toxic symptoms referable to the liver, and in this patient slight jaundice, which disappeared in about four days, was noted after two months of treatment. While synthalin is held to be of great use owing to its effects on the blood sugar following oral administration, the authors do not advocate the use of this drug indiscriminately in diabetes; they have employed it only for patients who could not be kept sugar-free on diet alone, and who were unwilling to take insulin. They insist, moreover, that it cannot and should not replace insulin, especially in the case of younger diabetic patients.

120. Intracardiac Blood Transfusion.

A. TZANCK (*Bull. de l'Acad. de Méd.*, May 27th, 1929, p. 630) reports a case in which a young woman on the verge of death from extreme haemorrhage was saved by intracardiac blood transfusion. Following an abortion so much blood was lost that the patient became unconscious; she was covered with cold perspiration, the pulse disappeared, the pupils dilated, and one or two sighing respirations were obviously the forerunners of death. In this emergency 650 grams of unaltered blood were injected into the heart, there being no time to determine the necessary type, nor could any vein be found. Quick restoration of colour followed and consciousness returned. The uterus was then plugged, but this caused a slight attack of faintness, which necessitated the further transfusion of 400 grams of blood intravenously, after verification of the blood group. The patient's subsequent convalescence was uneventful. The author recalls the case of this kind reported by Achard, Cournand, and Pichot. [See *Epitome*, March 30th, para. 320.].

Disease in Childhood.

121. Surgical Treatment of Empyema in Young Children.

A. FISCHER (*Zentralbl. f. Chir.*, March 16th, 1929, p. 656) refers to the very high mortality in children and infants suffering from empyema when treated by open drainage, and describes a method of closed drainage which he has used since 1925. He has treated 21 children, 8 of them under the age of 2 years, and has had only two deaths. The method is described as being quick and painless: it maintains a constant negative pressure in the pleural cavity, and it can be used in cases when open drainage would be dangerous—such as influenzal and pneumococcal empyemata. The disadvantages of closed drainage—the risk of the tube becoming blocked or kinked—are obviated by using metal tubes of a special pattern; these consist of a short, wide metal tube with stilette, and a narrower one which fits inside the first and can be fixed to it. Both tubes have side openings near the inner end and flat pieces at the outer ends; the inner tube is continued outwards so that rubber tubing may be attached to it. The site of election for insertion of the tubes is the seventh intercostal space at the posterior axillary line; if introduced more posteriorily the tube is apt to become kinked when the patient lies down, and if lower down the diaphragm may interfere with the inner opening after the effusion has decreased. The skin and tissues are infiltrated with a 1 per cent. novocain and adrenaline solution, and a test puncture is made to confirm the presence of pus. When this is detected a skin incision half to three-quarters of an inch long in line of the ribs is made, and the first tube with its stilette is inserted; after withdrawal of the stilette the opening of the tube is kept closed by the finger until the second tube is placed inside the first and fixed to it; attached to this one is a long rubber tube clamped at the end; this tube is led into a vessel which is at a lower level and half filled with antiseptic solution. The clamp is then loosened and the outer tube is fixed in position with bandages and plaster. This procedure, according to the author, has no ill effects on the child; on the contrary, the general condition improves rapidly. From the third day, or sooner if the tube blocks, the pleural cavity may be washed out with a mild non-toxic antiseptic. A certain degree of pneumothorax may develop gradually, but this is not dangerous owing to the formation of adhesions and the consequent shutting off of the inflammatory process and fixation of the mediastinum. Progress should be watched from the eighth day by x-ray examinations; if drainage is not complete the opening should be enlarged by resection of rib, which will now cause no disturbance. If drainage has been sufficient, the metal tube is removed on the tenth day, and a simple rubber drain is substituted.

122. C. CATTERUCCIA (*La Pediatria*, April 1st, 1929, p. 375) ives brief details of 41 cases of empyema in infancy reated by autogenous vaccines, principally by intravenous njection, and associated with evacuatory puncture or simple leurotomy. The results of this method of treatment were atisfactory, since 34 infants were cured and 7 died, 4 of hom were under 10 months old. The author states that in he milder cases puncture alone may be sufficient; in his iore severe cases injections were given on alternate days, nd if pleurotomy became necessary it was performed in he eighth or ninth intercostal space as far back as possible. n very septic cases the pleural cavity was washed out with hysiological saline solution. Fraenckel's diplococcus was resent in 37 and a streptococcus in 2 cases, associated in ne case with staphylococci.

123. Thyrotoxicosis in Childhood.

. GINSBURG (*Amer. Journ. Dis. Child.*, May, 1929, p. 923) elieves that thyrotoxicosis (toxic or exophthalmic goitre) is y no means so rare in childhood as is generally thought. hough it is generally milder and more atypical in its mani- estations than in adults, it may nevertheless run an acute ourse with a fatal issue. The author records details of arious cases he has observed, and discusses the diagnosis f the atypical forms. He finds that when the clinical sym- toms and signs, supplemented by laboratory investigations, re not decisive in distinguishing a simple from a toxic goitre, ne iodine and radium therapeutic diagnostic tests may be ery helpful. Surgical intervention in thyrotoxicosis cases children is not always successful and may be very danger- us. Ginsburg believes that radium therapy offers a safe nd dependable method which rivals medical treatment and rgical operation as regards successful results. He describes detail the treatment of several cases in this way which nd previously failed to respond to other therapeutical ocedures.

124. Acute Intussusception in Infants.

D. R. MURRAY (*Brit. Journ. Child. Dis.*, April-June, 1929, 83) records eight instances of acute intussusception in male fants aged from 3 to 22 months. In the case of six infants ged 12 months and under the patients were breast-fed, with e exception of a child who was being weaned during the eek prior to the onset of acute symptoms. Six of the hole series made an uninterrupted recovery after operation, cluding two children, each of whom had three intussus- ptions in the space of thirteen months; two died. In each these two the intussusception could be felt on rectal amination. Treatment in every instance was open reduc- on after laparotomy. In each case the wall of the lower d of the ileum (which was the starting point of each intus- sception) was markedly thickened, partly as the result of dematous infiltration, and partly as the result of swelling lymphoid tissue in this region. Dietetic errors were corded in the history of each case.

Obstetrics and Gynaecology.

125. Primary Epithelioma of the Vulva.

B. RENTSCHLER (*Annals of Surgery*, May, 1929, p. 703) views a series of 71 cases of primary epithelioma of the lva, and points out the rarity of the disease, the ratio to ncinoma of the cervix being 1 to 25. It is most common in ne sixth and seventh decades, but may occur much earlier. is doubtful whether trauma plays any significant part in ne causation of the condition, but it was found that 40 per nt. of the patients gave a history of chronic irritation such s pruritus; it may be supposed that the excoriation, abrasion, nd resultant pigmentation caused by the pruritus were the ndirect factors of the production of the epithelioma which eveloped subsequently. Epithelioma may also appear on reas of leucoplakia or on benign growths such as warts, heromas, and papillomas; in four cases kraurosis was resent. The first symptom is itching, followed by ulcera- on associated with pain, discharge, and slight bleeding; rinary incontinence and difficult micturition are common mptoms. Secondary anaemia and cachexia follow with ss of strength; other complications may be cystitis, lebitis, thrombosis of femoral vessels, with lymphoedema the legs and chronic septicaemia. Death usually follows ogressive failure and exhaustion. Epithelioma of the vulva ises most frequently from the labia majora on either side the vulva. Metastasis may be noted in the neighbouring eas of the vulva or in the perineum, the infection being rried through the lymphatics. Treatment must fit the dividual case, and if possible should be the wide excision of e growth and of the regional lymph nodes on both sides, llowed by the use of radium and *x* rays. When the lesion is too far advanced for removal, surgical diathermy, which is electro-coagulation, should be employed, or the intensive application of radium, or superficial and deep *x* rays. In the most advanced cases radium and *x* rays only are used; these give alleviation of pain and inhibition of the external growth for a time, but recurrence and the progressive course of the disease are inevitable. Prognosis is fair for prolongation of life, but poor for cure, and in direct proportion to the grade of malignancy. Out of 71 patients, 3 died following operation; a further 44 died from carcinoma, and one from relapsing pneumonia, which may have been a metastatic lesion. Six patients could not be traced, and the remaining 17 are still living, though one had a recurrence after eight years, one after four years, and one within a year after operation.

125. Diabetic Coma complicating Pregnancy.

DIABETIC coma as a complication of pregnancy is a rare condition; five cases alone have hitherto been reported, with only one recovery, in which insulin was used. M. S. MERRIAM (*Amer. Journ. Obstet. and Gynecol.*, May, 1929, p. 684) records another case with recovery following the use of insulin. The patient was given 120 units of insulin, 2,400 c.cm. of 5 per cent. glucose intravenously, and 1,500 c.cm. of saline by clysis, before coming out of the coma, which lasted twelve hours. About seven hours later she delivered herself of a stillborn foetus, and insulin was continued in doses of 15 units every three hours. From this time the patient showed continued improvement, and ultimately recovered. For the following year it was found necessary to give her 15 to 30 units of insulin daily, but during the past year the condition has been controlled entirely by diet. Merriam states that even very mild diabetics may suddenly go into coma during pregnancy, and that young diabetics, especially when the condition is aggravated during their menstrual periods, have the worst prognoses. The use of insulin results in marked improvement immediately after delivery, similar to that noted in the toxaemias of pregnancy. However, the death of the foetus before delivery makes the prognosis much more grave, because, while the foetus is alive, the foetal pancreas helps the mother in the carbohydrate metabolism. Operative delivery during diabetic coma would seem to have as serious a prognosis as in eclampsia.

127. Local Treatment of Puerperal Infection.

LOP (*Bull. Soc. de Thér.*, April 10th, 1929, p. 113) maintains that local treatment should not be entirely omitted in puerperal infection, and that it may yield excellent results if combined with vaccine and serum treatment and fixation abscesses. In mild cases Delbet's vaccine or large doses of antistreptococcal serum may be sufficient, but when these are inadequate local treatment is indicated. Lop recommends two or three intrauterine irrigations in the twenty-four hours with sterilized water or normal saline solution at a temperature ranging from 96.8° to 104°. The irrigations should be given by a rubber intestinal tube, and two or three litres of fluid should be used. When the lochia are very fetid a solution of potassium permanganate in a 1, 2, or even 3 per 1,000 dilution should be employed. Antiflexion of the uterus, which is almost always present, should first be corrected by slow and continuous abdominal pressure, so as to restore the uterus to its proper position and enable its secretions to drain away.

128. Endometriosis.

J. V. MEIGS (*New England Journ. of Med.*, May 16th, 1929, p. 1020) believes that endometrioma of the abdominal wall is not an infrequent occurrence, and that it is probably a preventable lesion; he reports four cases of this condition. Aberrant endometrium may be found in many regions in the pelvis and in a few outside it. It is frequently seen in the uterine wall, the ovary, and the recto-vaginal septum. The condition also occurs in many other areas of the pelvic peritoneum, the tubes, the sigmoid, the appendix, the umbilicus, and occasionally in the inguinal canal and vulva; lesions have also been found in abdominal scars. The etiology of all these growths is probably the same. They are likely to be due to transplantation of endometrial tissue either from the uterus or ovarian haematomas, or from growths from "rests" of the Müllerian or Wolffian bodies in the pelvis which have been stimulated into activity by some unknown substance. This excitant may be the ovarian secretions, the menstrual blood, or some other substance. A typical endometrioma is a firm, hard tumour without capsule, which on gross section shows small cystic areas containing bloody fluid, and microscopically a glandular structure with characteristic uterine stroma about it, and frequently areas of smooth muscle. Numerous theories have been advanced to explain endometriosis, but none account for the presence of all aberrant endometrium. The finding of endometriomata in operative scars seems to substantiate Sampson's theory of implantation; but there are so few cases, in comparison with

the great number of operations in which the endometrium is exposed or cut across, that some other factor besides implantation may be necessary for the growth of the lesions. Microscopical diagnosis is easy, and diagnostic curettage is very important. The treatment consists in entire removal of the lesions, or in total ovarian ablation either by removal of the ovaries or by their irradiation to the menopausal dose. Greater protection of the abdominal wound during pelvic operations would probably prevent some scar endometriomata. The prognosis is excellent if the lesion is definitely understood and correct methods are used either to remove it or to cause cessation and atrophy of the growth.

Pathology.

129. Resistance of the Diphtheria Bacillus.

P. LOMRY (*C. R. Soc. de Biologie*, May 17th, 1929, p. 161) during a period of three years conducted a number of investigations on the vitality of twenty strains of the diphtheria bacillus and the retention of its virulence in the throat in nutrient media, water, and on various substances. From the study of 10,000 throat swabs he found that 90 per cent. of patients remain carriers for five or six weeks, 9.9 per cent. for three or four months, and 0.9 per cent. for one or two years. The virulence of the bacillus varies considerably in different individuals, but as a general rule it diminishes with age in the same throat. On nutrient media, such as agar, serum, and broth, the bacillus retains its virulence for many months—a year or more. Lomry filled test tubes with water derived from snow, rain, wells, rivers, and ponds, boiled or not, and inoculated them with a loopful of a fresh culture of diphtheria bacilli. He found that as a rule the bacilli were killed after three days at the ordinary temperature, and after thirty hours at 37° C. Inoculation of various objects, such as pieces of wool, cotton, wood, or metal, with broth cultures showed that the diphtheria bacillus survived for fifteen to twenty-five days. Some strains died on the tenth day, while others lasted to the thirtieth. The average duration was ten to twenty days, but before death the bacilli lost much of their virulence. Lomry has not found any previous references in literature to the vitality of the diphtheria bacillus in water. His observations regarding its persistence in the throat and on nutrient media agree with those of previous investigators, but the results obtained by *desiccation* differ from those of most of his predecessors.

130. The Effect of Liver Feeding on the Blood Sugar Content.

IN continuation of a previous preliminary report, H. BLOTNER and W. P. MURPHY (*Journ. Amer. Med. Assoc.*, April 20th, 1929, p. 1332) now report in further detail observations on the effect of liver on the blood sugar levels in 18 cases of diabetes, 9 of primary and secondary anaemia, and in 2 normal persons. The similarity of certain symptoms (marked hunger, headache, nervousness, and sweating) after liver treatment in some cases of pernicious anaemia to those of hypoglycaemia led to this study. A comparison was also made of the relative effects of insulin, liver, and various liver extracts in certain cases. The blood sugar concentration was determined by the Folin-Wu method in a morning fasting specimen, and usually three, six, and nine hours following the ingestion of a uniform test meal; and on another day, at the same intervals, after a test meal containing 180 grams of raw liver pulp. It was found that the liver had the effect of lowering the blood sugar level. Hunger, headache of varying intensity, and slight dizziness were outstanding complaints which all the patients made six and nine hours after the liver test meal, and these symptoms, not noticeable after the control meal, were possibly attributable to the rapid lowering of the blood sugar level. These observations suggest that liver contains a blood sugar reducing substance when taken by the mouth, which is non-toxic and has an effect on the blood sugar concentration similar to that obtained with insulin. It is difficult to estimate the quantity of liver that will replace a known amount of insulin, but the authors believe that 180 grams of liver will have an effect on the blood sugar of certain diabetic patients equal to that of from 10 to 15 units of insulin.

131. Precipitable Substances in Bacilli of the Salmonella Group.

J. FURTH and K. LANDSTEINER (*Journ. Exper. Med.*, May, 1929, p. 727), working with organisms of the salmonella group, have succeeded in isolating from them specific precipitable substances which appear to be of carbohydrate nature. Three methods of extraction were employed: (1) with alkaline hypochlorite solution; (2) with boiling saline solution, and (3) by autoclaving with subsequent tryptic digestion. The substances obtained by one or other of these methods were tested against immune serums prepared by the injection of rabbits with whole cultures killed by heating to 62–65° C. for forty minutes. Though there was a certain amount of cross-precipitation, the results showed clearly that the strains fell into three groups: the first contained *B. typhosus* and *B. enteritidis*; the second *B. paratyphosus* B and the Derby bacillus; and the third *B. suipestifer* and the Newport bacillus. The precipitable substances derived from *B. abortivo-equinus* and from the Stanley and Reading types behaved like *B. paratyphosus* B. A comparison of these results with those obtained by Bruce White in this country, using the agglutination reaction, shows a substantial measure of agreement in the grouping of the salmonella bacilli. It would therefore appear probable that the precipitable substances correspond to the heat-stable or O agglutinogens. This probability is increased by the finding that absorption of an immune serum against *B. typhosus* with alcohol-treated *B. enteritidis* removes the O but not the H agglutinins from the serum. Chemical examination of the precipitable substances showed that they were rich in carbohydrate but contained little or no protein. Though differing markedly in their serological reactions, chemically they were more or less indistinguishable. In this respect they differ from the polysaccharides extracted from different types of pneumococci.

132. Experimental Amyloid Degeneration.

E. PUCCINELLI (*Lo Sperimentale*, May 10th, 1929, p. 213) has produced amyloid degeneration in rats by the intraperitoneal injection of nutrose. Thirty-two rats were treated, and after twenty to forty injections small portions of the spleen were removed from each animal. In twelve no trace of amyloid deposit was detected; in twenty the spleens showed commencing amyloid changes in varying amounts. The injections were then discontinued. Three months later only seven rats were alive; the remaining thirteen had died within the first fifty days. The spleens of these thirteen rats all showed characteristic foci of amyloid degeneration in the spleen similar to those observed at the biopsies. The seven survivors were killed and found to be free from all trace of amyloid disease, the spleens having returned to normal size. In some the lymph follicles were enlarged; in the pulp were megakaryocytes, cells containing pigment giving the iron reaction, and also small clusters of cells with excentric nuclei resembling plasma cells. The other organs appeared healthy. The author regards these results as demonstration of perfect regression—an example of reversibility of amyloid degeneration. Histologically, the regression was independent of any phagocytic action. During the reabsorption he was unable to detect any modification of the staining reaction of the amyloid substance such as has been described by other workers.

133. Alkali Load as a Test of the Kidney Function.

A. SYLLA (*Deut. med. Woch.*, May 10th, 1929, p. 783) administered 20 grams of sodium bicarbonate in 400 c.cm. of water by the mouth and estimated the *p*H of the urine when starving, and at the four subsequent half-hours, after eight hours, and after twenty-four hours, using Walpole's comparator and Michaeli's test tubes. With healthy kidneys the *p*H was about 5.8 when starving; half an hour after the alkali load it rose to 7.2; after an hour it was 8.4; and it afterwards slowly fell. The rising of the *p*H curve was usually slower in elderly persons. In 31 cases with various morbid conditions of the kidney the alkali excretion was delayed and diminished in 17 cases, and a *p*H of 8.4 was never reached. In patients with high blood pressure, and cases of hyper-acidity, the alkali excretion was also delayed and diminished; whether in the last class this is influenced by the secretion of the stomach is a disputed point. The author recommends the test as a simple way of estimating renal function.

134. Neutralization of Tetanus Toxin with Glucose.

M. GAROFEANU and P. IONESCU (*C. R. Soc. de Biologie*, May 24th, 1929, p. 227), in view of recent reports on the beneficial action of intravenous inoculations of glucose in cases of tetanus in the horse, have examined the neutralizing power of glucose on tetanus toxin *in vitro*. Using the mouse as the test animal, it was found that 10 mg. or more of glucose—added in a 20 per cent. solution—were able to neutralize one minimal lethal dose of toxin. Neutralization was sufficiently complete after one hour's sojourn at room temperature to protect the animal from death. When two minimal lethal doses of toxin were used it was found that even 50 mg. of glucose failed to neutralize it completely. Mice injected with the toxin-glucose mixtures all died, though their survival time was considerably greater than that of the control animals. How the neutralizing action of the glucose is exerted was not determined, but it does not appear to be due to alterations in the *p*H of the toxin.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus sylvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

The Natural Sedative Emollient
DUSTING POWDER.
Impalpable, Inorganic, Absorbent.

In Skin Affections

During the eruptive and irritating stages of Measles and Scarlet Fever, and following Vaccination, marked relief is afforded by applications of Emol-Keleet. Purulent Eczema and Inflammatory Papulæ, too, are greatly ameliorated by its sedative and absorbent action.

Samples free to the Medical Profession on request.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to th

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56. Northampton), who can be seen in London by appointment.

HAYDOCK LODGE
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

NEURASTHENIA
BELVOIR NURSING HOME, ASTON-ON-TRENT, DERBY.

Private Nursing Home for Neurasthenia and allied Functional Nervous Disorders, for general Convalescent Cases, and those requiring Electrical Treatment.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, Ultra-violet Light, and Massage is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week. For further particulars apply to—
Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.
Dr. Douglas-Morris can be seen by appointment in London.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

MAUDSLEY HOSPITAL,
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.
IN-PATIENTS: (*a*) 160 beds (both sexes) in wards or separate rooms. (*b*) 13 private rooms (for ladies) with special sitting room, garden, and dietary.

Terms:

(*a*) £5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.
(*b*) £6 6s. a week.

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., M.R.C.P., F.R.C.S., Medical Superintendent.

UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE

(Associated with the General, Queen's, and Special Hospitals for Clinical Teaching.)

THE SESSION OPENS ON MONDAY, SEPTEMBER 30th, 1929.

The University grants Degrees in Medicine, Surgery, and Public Health, and a Diploma in Public Health; also Degrees and a Diploma in Dental Surgery.

The courses of instruction are also adapted to meet the requirements of other Universities and Licensing Bodies.

HOSPITAL APPOINTMENTS.

A large number of Resident Hospital appointments in Birmingham and District are open to qualified students of the School.

SCHOLARSHIPS, EXHIBITIONS, AND PRIZES.

Entrance and other Scholarships and Exhibitions and various Prizes and Medals are awarded annually in the Faculty of Medicine.

SCHOOL OF DENTISTRY. (University of Birmingham and Birmingham Dental Hospital.)

The School of Dentistry, in conjunction with the General and Queen's Hospitals, affords a complete curriculum for the Dental Diplomas and Dental Degrees of the University and all other Licensing Bodies. There is a Dental Scholarship of the value of £46 17s. 6d. offered annually.

PRE-MEDICAL AND PRE-DENTAL EXAMINATIONS.

The necessary Courses of Instruction in Chemistry and Physics and in Biology may be attended in the University.

RESIDENCE FOR UNDERGRADUATES AND OTHER STUDENTS.

There are Halls of Residence for Men and for Women Students. A register of approved lodgings is also kept by the Secretary of the University.

For Syllabus and further information apply to Prof. J. C. BRASH, M.A., M.D., Dean.

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL.

THE WINTER SESSION will Open on Tuesday, October 1st.

The Hospital is the largest in England. There are 839 beds in constant use. Last year: number of in-patients 14,698; new out-patients, 96,928; attendances, 555,762; new dental patients, 5,857; major operations, 7,649.

The MEDICAL COLLEGE and DENTAL SCHOOL are essentially modern, with large laboratories equipped with the latest and the most approved appliances. *The STAFF is so large as to permit of individual attention being paid to all Students.*

MEDICAL UNIT.—A Clinical Unit in Medicine, under the charge of a whole-time Director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co ordination of medical research.

RESEARCH FUNDS to the value of over £113,000 permit of financial assistance being given to Students and Graduates engaged in Medical Research.

SCHOLARSHIPS and PRIZES to the value of £1,158 are awarded annually, including four Open Entrance Scholarships to the value of £350, and two Entrance Scholarships open to students of the Universities of Oxford and Cambridge to the value of £200.

APPOINTMENTS.—Over 160 Appointments are made annually from Students of the College recently qualified.

SPECIAL COURSES are held for all the University Examinations, for the Primary and Final Fellowship Examinations of the Royal College of Surgeons, and for the Membership Examination of the Royal College of Physicians.

HOSPITAL PRACTICE.—Exceptional opportunities are offered to qualified Practitioners wishing to attend the General Practice or the Practice of a Special Department of the Hospital.

A Clubs' Union, an Athletic Ground of over 13 acres, and a *Students' Hostel*, promote the recreation, health, and comfort of the Students.

For Prospectus and Particulars apply to the Dean (Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S.), who will be pleased to make arrangements for anyone wishing to see the Medical College and Dental School.

MILE END, E.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel: Langham 1166.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) CH.M.EDINBURGH. M.C.CANTAB. F.R.C.S.EDINBURGH. M.S.LONDON.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

APPOINTMENT OF COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the West Riding of Yorkshire invite applications for the appointment of Medical Officer of Health for the County.

The commencing salary will be £1,600 per annum.

Candidates must not only be duly qualified as prescribed by the Local Government Act, 1888, but must also possess considerable administrative capacity, and a wide knowledge and experience of the organization of Public Health work.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the successful applicant will be required to pass a medical examination.

Canvassing, directly or indirectly, will be a disqualification.

Particulars of qualifications and duties of the office, and terms and conditions of service and forms of application, may be obtained from the undersigned, and applications (on forms supplied), together with copies of not more than three recent testimonials, should be sent, marked "Confidential," not later than August 31st, to the Clerk of the County Council, County Hall, Wakefield.

J. CHARLES McGRATH.

July 23rd, 1929.

COLONIAL MEDICAL SERVICES.

Vacancies exist at present for MEDICAL OFFICERS in:—

(*a*) THE WEST AFRICAN MEDICAL STAFF.

(*b*) THE MALAYAN MEDICAL SERVICE.

QUALIFICATIONS.

Applicants must be British subjects of European parentage and between 22 and 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held hospital or public health appointments, or who have special knowledge of anæsthetics, radiology, surgery, medicine, ophthalmology, gynæcology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

COURSES OF STUDY.

Selected candidates will be required to take a special course of study in tropical medicine and hygiene commencing in October, either at the London School of Hygiene and Tropical Medicine or at the Liverpool School of Tropical Medicine, or at the University of Edinburgh, before taking up their appointments. Tuition fees will be paid and an allowance granted by Government subject to certain conditions.

Further particulars and forms of application may be obtained, on application in writing, from the PRIVATE SECRETARY (APPOINTMENTS), COLONIAL OFFICE, 2, Richmond Terrace, Whitehall, London, S.W.1.

University of Sydney.

The Senate invites applications from gentlemen qualified to hold the BOSCH CHAIR OF SURGERY, the duties of which commence on March 1st, 1930. THE MECHANICS OF THE DIGESTIVE TRACT

ALVAREZ has shown how very sensitive is the rectum to any increase in internal pressure. Very slight abnormality of distension suffices to produce headache and a feeling of malaise. Zimmerman found that a rise in rectal pressure of even so little as 3 mm. of mercury produces a definite effect on consciousness.

No matter what may be the explanation of these psychic manifestations of constipation, there is no doubt that the abdominal discomfort associated therewith is almost entirely due to disturbances in the tone and rhythmic movements of the intestinal wall.

Both groups of symptoms can nearly always be avoided or removed by a regular morning glass of Eno's "Fruit Salt," taken just before the early cup of tea. This draught is pleasant and refreshing; and, by retaining fluid in the bowel, promotes steady and harmonious peristalsis and gentle and painless elimination. Being free from all admixture of the unpleasant mineral sulphates (Epsom and Glauber), Eno has no need of sugar or artificial flavouring agents to disguise its natural taste. Its freedom from sugar makes it a specially suitable preparation for use in diabetes.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "THE DOCTOR'S EMERGENCY REMINDER" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

Digifortis

A Superior Digitalis Preparation. Physiologically Standardised.

FEW preparations are more prone to deterioration than tincture of digitalis. Hence the necessity for specifying a dependable tincture in order to secure full results.

"Digifortis"— a digitalis tincture which is 50% stronger than the B.P. tincture—merits medical specification because of the exceptional precautionary measures taken to maintain its effectiveness. They may be summarised as follows:—

1. Each package is stamped with the date of manufacture to obviate inadvertent use of a deteriorated specimen.
2. The tincture is standardised physiologically by the Houghton frog-heart method.
3. It is rendered fat-free during manufacture and is thus more stable and less irritating.
4. Only 1-oz. bottles are supplied, allowing complete consumption before extensive deterioration can occur.
5. Amber-glass containers are used to counteract actinic ray activity and the space between the stopper and liquid is filled with an inert gas, to preclude oxidation.

A booklet outlining the uses of Digifortis, including recent methods of rapid digitalisation, will be sent on request.

DIGIFORTIS TABLETS contain powdered digitalis leaves especially selected for high potency. Each tablet represents 10 minims of the liquid Digifortis. In bottles of 50.

PARKE, DAVIS & CO. 50 BEAK ST., LONDON, W.1.

Insured Against Imitation!

The Antiphlogistine Container, in its present form, is scientifically designed and was adopted after years *of painstaking research.* Drawn of special alloyed metal with neither seams nor joints and hermetically sealed by an easily removable metal cap and ring, the physician is assured of a highly efficient container, on the one hand, maintaining the hygroscopic potency of its active ingredients and preserving them against oxidation or deterioration even under the severest climatic conditions, and, on the other hand, furnishing a distinctly convenient method for heating the contents whenever and wherever the emergency may arise.

Rigid laboratory control at all times and at every step in its production guarantees uniformity of therapeutic action. That more and more doctors are to-day turning to Antiphlogistine is convincing proof that it meets the exacting requisites of the modern practitioner for a safe and efficient poultice and dressing.

The originality and uniqueness of the Antiphlogistine container obviates confusion and protects *your* patient against package imitation.

There is only one Antiphlogistine!

& the Original!

LONDON: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health ... and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition.... MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

Refer your Patients also to

RADIUM

For Therapeutic & Physical Purposes

We are the sole agents for the British Empire (excluding Canada) of the Anglo-Belgian Mining Corporation, The Union Miniere du Haut Katanga (Radium Section), the producers of practically the whole of the world's output of radium. We are prepared to give information and advice regarding the use of radium, and to supply radium in any form, accompanied by an official signed guarantee of measurement and purity. We have during the past few years supplied practically all the large hospitals using radium and also the leading radium therapists and physicists.

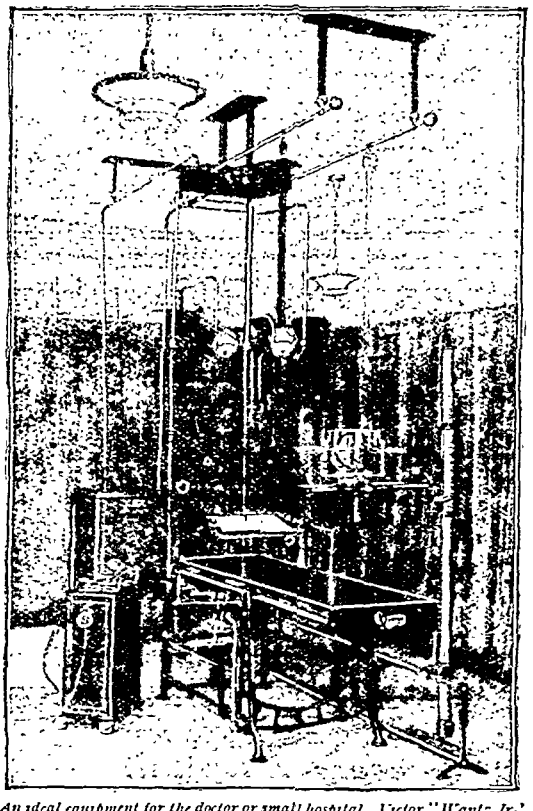
X-RAY REPUTATION

FOR THERAPY 5 mA at 115 kVP



FOR RADIOGRAPHY 100 mA at 100 kVP

An ideal equipment for the doctor or small hospital. Victor "Wantz Jr." X-Ray Machine in combination with Victor Model 9 Table.

Prestige and Its Obligations

Many important advances in X-ray technique have become possible through improved apparatus as developed by Victor research. Yet the name Victor has never been associated with a failure or with questionable X-ray equipment.

Every piece of apparatus developed by Victor is submitted to searching tests in actual practice. Not until it has successfully withstood these tests is it offered to the medical profession.

The Victor X-Ray Corporation has never jeopardized its own prestige or that of the doctor who turns to it for apparatus or technical counsel.

May we send you literature or give you a demonstration at our showrooms?

VICTOR X-RAY CORPORATION Ltd.

Morley House, 320, Regent Street (Oxford Circus), London, W.1

Telephone: MAYFAIR 6554. *Telegrams:* STABILIZER.

VICTOR

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

HOME TESTS ARRANGED FOR DOCTORS AND PATIENTS

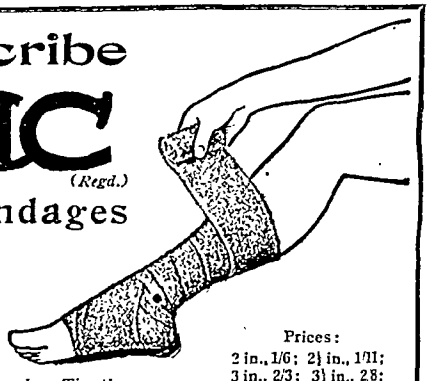
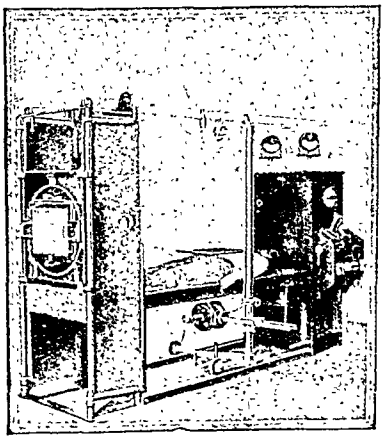
Blue Carton Crêpe Bandages

For varicose veins and in all cases where support is needed. Fully guaranteed and exceptionally elastic. The "Flesh Colour" is almost invisible under silk stockings.



Stocked by all Chemists and Druggists, Boots 800 Branches, Timothy White Ltd., Taylor's Drug Stores, and Parkes Chemists Ltd.

Prices:
2 in., 1/6; 2½ in., 1/11;
3 in., 2/3; 3½ in., 2/8;
4 in., 3/-.



Now available for every Hospital.

The acme of Simplicity.

The NINETY-THIRTY **X-RAY APPARATUS**

Certified by NATIONAL PHYSICAL LABORATORIES as complying with RECOMMENDATIONS OF THE X-RAY COMMITTEE ON PROTECTION.

The power of the apparatus here shown is 90 kilo-volts at 30 milliamperes and is therefore capable of meeting the requirements of any hospital for diagnostic radiography and fluoroscopy.

The floor space occupied by the complete installation is only 9 ft. × 2 ft. and is therefore suitable for any X-ray room.

The operation of the outfit is so simple that any doctor can obtain radiograms of first-class quality even though he may have had no previous experience. The difficulties associated with X-ray work in the past are now entirely overcome by a device known as the "Automatic Technique Director" which indicates the exact setting of the controls for radiographing any part of the body. The outfit includes a full set of accessories, dark room equipment, etc., and thus COMPRISES A COMPLETE INSTALLATION.

PRICE complete, as illustrated, for use on Alternating Current, including all Accessories **£350**

Ditto, Apparatus for use on Direct Current **£410**

The outfit can be supplied with Metalix X-Ray tube instead of Coolidge X-Ray tube at an additional charge of **£10.**

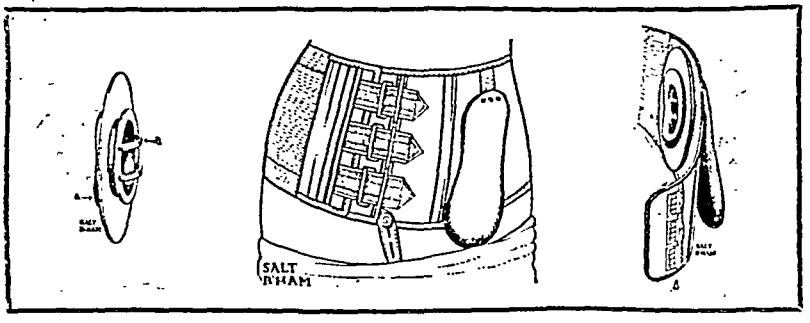
SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

SALTS' PATENT COLOSTOMY BELT



The fact that many Hospitals and Surgeons are now prescribing Salts' Patent Colostomy Belt and the vast increase in Repeat Orders goes to prove, conclusively, the efficiency of this up-to date Salt appliance.

ADVANTAGES

1. Detachable receiver sterilizable by boiling.
2. Mouth of bag kept open for free entry of fæces.
3. Easy removal and cleaning of bag, without removal of belt.
4. No crevices to hold fæces, and therefore little odour.
5. Less bulk, greater comfort, and more sanitary than any other.
6. Rubber portions far more durable than in the old style belt.

Spare Bags are easily and quickly obtainable at low cost.

COLLECTING OVERDUE ACCOUNTS "WITHOUT OFFENCE"

Often debtors do not pay because of the way they are approached for a settlement. A bullying manner, or too curt a letter, will not only make a Client seek new Professional attendance—he will also forbear paying as long as possible.

Below is a copy of a letter from a debtor whom one of our Members originally tried to collect from in the wrong way.

Dear Sir,

As regards the enclosed, I should have paid long ago had it not been for what I consider the very unprofessional procedure meted out to me.

I now enclose my cheque.

Yours faithfully,

BRITISH MEDICAL PROTECTION SOCIETY

(B.M.P.S., Ltd.)

'Phone MUSEUM 4228

Secretary: N. RUTHERFORD WATSON.

ESTABLISHED 1891.

4, MARGARET STREET, CAVENDISH SQUARE, LONDON, W.1

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Novopine Sparkling Pine Bath Tablets

for nervous & heart disorders, rheumatic conditions, etc., etc.

INTESTINAL SUBINFECTION

SALVITAE is the key whereby the physician may control elimination and alkalinization, thus dealing fundamentally and effectively with Intestinal Subinfection, Toxæmia, Acidosis, Uric-acidæmia, and Constipation.

It is indicated in a large number of disorders characterized by, and more or less dependent upon, faulty metabolism, imperfect elimination, and disturbances of the acid-base equilibrium of the body.

Samples and Literature on request to Sole Agents:

In all cases of auto-intoxication

Diabetes, rheumatism, gout, sciatica, lumbago, neuritis and many other similar diseases have been found to have their origin in auto-intoxication, which gives rise to acidosis. ¶ The speedy and thorough evacuations induced by Sal Hepatica expel all auto-intoxicants from the system, while the blood and urine is rendered alkaline. ¶ Sal Hepatica stimulates the biliary flow, thereby relieving hepatic congestion, and restores the daily habit of defecation by natural means. It is non-habit-forming, non-irritant and entirely painless in its action. Sal Hepatica is only advertised to the medical profession.

Sal Hepatica

the proved medicinal saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to

BRISTOL-MYERS COMPANY, 112, Cheapside, London, E.C.2.

Intestinal Disinfection

PREVENTION OF CANCER

ONE of the most noted authorities on Alimentary Toxæmia is firmly convinced of the importance of this condition in the production of Cancer.

The irritant effects of the stagnating contents of the bowel on the intestinal mucous membrane, accompanied as it often is with ulceration, is obviously a cause of Cancer in the bowel itself. According to this writer, the toxins absorbed produce atrophic changes in the breast and other organs which are specially prone to be followed by Cancer.

There are grounds, therefore, for hoping that the use of the most efficient of all intestinal disinfectants—Kerol—for prevention and cure of alimentary toxæmia, will do much to prevent the occurrence of Cancer.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

THE KAYLENE TREATMENT

The following letter has been received recently.

MESSRS. KAYLENE, LTD. April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

Literature and supply for clinical trial obtainable from the manufacturers:

INSULIN "A.B."

TRADE A.B. MARK **Brand**

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B" Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.

Supplied in two strengths:

20 units per c.c.

Packed in bottles containing:

5 c.c. (100 units or 10 doses) 2/- each
10 c.c. (200 „ 20 „) 4/- „
25 c.c. (500 „ 50 „) 10/- „

40 units per c.c.

Packed in bottles containing:

5 c.c. (200 units or 20 doses) 4/- each

Full particulars and the latest literature will be sent free to members of the Medical Profession.

"AFTER TAKING BEMAX I FELT FIT AFTER THREE DAYS."

(D.12) "I take Bemax myself, sometimes raw and sometimes with milk. When I began I was run down, but after taking Bemax I felt fit after three days." F.R.C.S.I.

(3D) "I take Bemax myself and have continued to take it as I find it so beneficial. I take it with porridge and milk. When I began taking Bemax the effect was noted in a few days. I felt better and stronger, and better able to bear fatigue. I have much pleasure in recommending it to my patients and I have had pleasing results." M.D., D.P.H.

Bemax is now established as the B vitamin food. Over 27,000 members of the medical profession are taking Bemax themselves or prescribing it for their patients, with excellent results. The diseases for which medical men are prescribing Bemax are Constipation, Intestinal Toxæmia, Debility, Neurasthenia, Rheumatism, Gastric disturbances and all forms of skin disease. In fact, any ailment due to B-vitamin deficiency. If you have not tried Bemax, a free full-size tin will be sent you on receipt of your professional card.

BOOTS PRODUCTS

Hexyl-Resorcinol (BOOTS)

V. L. and W. A. F. (*Surg., Gynæcol. and Obstet., November*, 1927, *p.* 603) consider that Hexyl-Resorcinol, in addition to being a urinary antiseptic, can be used with advantage in other conditions where a non-toxic bactericidal agent is required.

***The solution recommended contains 30 per cent. of glycerin and 70 per cent. of water; in each cubic centimetre is dissolved 1 mg. of crystalline Hexyl-Resorcinol.**

This solution was found to be stable and to destroy most pathogenic micro-organisms in less than fifteen seconds. **The surface tension is very low, and the Hexyl-Resorcinol remains in perfect solution in all dilutions.**

***HEXYL-RESORCINOL-BOOTS IN GLYCERIN is available in ¼-pint, ½-pint and 1 pint bottles.**

HEXYL-RESORCINOL (BOOTS) is supplied in Enteric-coated Tablets—in bottles of 25 and 100 tablets.

Special Gelatin Capsules—in boxes of 24 and 100 capsules—are also available.

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

K.Y. LUBRICATING JELLY

K.Y. Lubricating Jelly reduces the discomfort of instrument-introduction far more efficiently than petrolatum. It is more "slippery," flows more easily, and never binds. It is contained in a convenient compressible tube, which protects it from the air and enables the exact amount needed to be squeezed out quickly and hygienically. K.Y. Jelly is greaseless, non-staining, and water soluble. It is prepared from certain vegetable substances blended in correctly balanced proportions with boric acid, and does not irritate the skin or interfere with the application of local remedies.
Obtainable from medical supply firms and pharmacists throughout the world.
Write for samples, stating name of your local supply house.

Wholesale and Export Druggists and Manufacturing Chemists.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat"

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

Cow & Gate Milk Food

PACKED IN A BLUE TIN

This food has the following composition:—

	Dry Food	Reconstituted (1 part in 8 parts of water)
Fat - - -	15.5 ...	... 1.7
Proteins - -	20.0 ...	... 2.2
Lactose - -	58.0 ...	... 6.4
Mineral Matter -	4.5 ...	... 0.5

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The manufacturers will gladly supply samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

EXAMPLE OF THE MOST ANCIENT INDIGENOUS ART OF INDIA.—Of the monument here illustrated one of the first English students of Indian architecture and art wrote: "It cannot be too strongly insisted that the art here displayed is purely indigenous. The capitals of the pillars do resemble somewhat those of Persepolis, and the honeysuckle ornaments point in the same direction; but, barring that, the art, especially in the figure sculpture belonging to the rail, seems an art elaborated on the spot by Indians, and by Indians only." Archæologists are not agreed on this judgment. Those opposed argue that Hellenistic influence had already reached central India and that from it the native artists drew vitality and inspiration. While further investigation may help to determine which view is correct, there is little evidence of Western influence in the work itself, which, while crude, displays great charm and vigour.

VITAMINS A, B & D
HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

A Paper on SYPHILIS OF THE HEART AND AORTA.*

BY

JOHN COWAN, M.D., AND J. STEVEN FAULDS, M.B.

(From the Royal Infirmary, Glasgow.)

IT is extremely difficult to assess the importance of syphilis as a cause of heart disease. We have little knowledge of its incidence among the general population, and still less of its influence upon the heart. In consequence we do not know whether the cases which we recognize as syphilitic heart disease are merely isolated curiosities or the common sequel of uncured syphilis.

The immediate mortality of syphilis is trifling; it kills through visceral complications. But no one indicates the specific nature of the organic disease upon the death certificate, and cirrhosis of the liver, cerebral disease, etc., figure on the records. The mortality of syphilis must, however, be considerable, for aneurysm alone kills a thousand people every year in England and Wales, and the vast majority of fatal aneurysms are due to syphilis.

The disease is common. Osler and Macrae[1] state that it has been estimated that 12 per cent. of the adult population in Berlin and 15 per cent. in Paris are affected, while in America the incidence is said to vary between 6 and 40 per cent., a positive Wassermann reaction being present in 15 per cent. of hospital patients. Though in England statistics are less numerous, it is known that about 100,000 men of our armies in the last war were infected,[2] and "as it is reasonable to suppose that more venereal disease was imported into France than vice versa," the incidence at home must be considerable. In our wards routine Wassermann tests showed positive results in 8.6 per cent. of the male, and 7.2 per cent. of the female patients, quite irrespective of their ailments.

The influence of syphilis in heart disease is evidently considerable. Carey Coombs[3] states that syphilis was present in 9 per cent. of his hospital, and 4 per cent. of his private, patients. Allan[4] states that a syphilitic infection was present in 63 of 320 cases of "failing heart" admitted into hospital (19.7 per cent.). Our own figures, in a series of 395 cases of organic valvular disease, show a syphilitic incidence of 17.7 per cent. Routine Wassermann tests have shown that the incidence is much greater than was formerly supposed.

The evidence from the pathological side suggests that the higher figures are the more accurate. In our series of 390 cases presenting naked-eye signs of cardio-vascular disease 60 (15.3 per cent.) were syphilitic. It must be remembered that these figures are a conservative estimate, for a negative Wassermann reaction does not prove that syphilis has not been active in the past, and the results of syphilis cannot always be recognized as syphilitic after death. Any part of the heart may be affected, and any disease of the heart may be due to syphilis. In some diseases syphilis is the common cause, in others the exception.

THE PATHOLOGICAL LESIONS.

The chief pathological lesions are: endarteritis obliterans, aortitis, aortic valvular disease, gumma of the heart, and myocardial fibrosis. The other lesions are rarely syphilitic. We have analysed a series of 1,000 consecutive necropsies. Of these cases 390 presented some disease of the heart or aorta, judged by naked-eye examination. These lesions were not, however, necessarily the cause of death, some of the patients having died from pneumonia, cancer, etc. Of these 390 cases 60 presented some evidence of syphilitic heart disease.

Endarteritis Obliterans.

Endarteritis obliterans occurs chiefly in the smaller arteries and the arterioles. It is always local in its distribution, and never affects more than a short length of a vessel, but, as it affects the whole circumference of the wall, the lumen is always narrowed, and not infrequently completely blocked, usually by thrombosis.

In this lesion the *intima* is always thickened, the new-formed connective tissue being in the early stage loose and cellular, with much hyperplasia of the elastic elements. In the later stages it is poorly nucleated and hyaline, with degeneration of the elastic tissue. The *media* may be little altered or greatly thinned. The *adventitia* is always thickened, sometimes to an extraordinary degree, and, like the intima, shows new formation of elastic tissue. The relative thickness of the intima and the adventitia varies considerably in different cases, sometimes the one and sometimes the other showing the maximal change. Gross calcareous and fatty changes are rarely found.

Muir[5] states that this lesion represents the ordinary reaction of the arterial wall to an irritant, which often approaches it from without. It is common in the vicinity of an ulcerative process, in pulmonary silicosis, tuberculous lesions, and granular kidneys. It is perhaps the special arterial lesion in syphilis, and occurs at all stages of the disease, in the chancre as well as in the tertiary lesions. It is always present in gummata, and occurs as well in their absence. Its occurrence in the adventitia of the aorta, and in the arteries of the heart, plays an important part in the causation of aneurysm and of ischaemic fibrosis of the myocardium.

Syphilitic Aortitis.

The syphilitic lesions in the aorta occur as soft elevated plaques, usually sharply circumscribed, and of considerable thickness. They have a greyish, gelatinous appearance, and as they extend and fuse may affect considerable tracts. In older specimens, where absorption and contraction have ensued, the plaques are thin and pearly white; the ultimate cicatrix has sometimes a stellate appearance. The thoracic aorta, in particular its first part, is most often involved, and this selection is unfortunate, as a spread downwards is likely to involve the orifices of the coronary arteries or the aortic cusps, with resultant ischaemia of the cardiac muscle or aortic valvular disease. The aortic wall, too, is always weakened, and syphilitic aortitis is thus the common cause of aortic aneurysm.

The early lesions in the aorta are, however, not intimal but adventitial. The earliest change consists of an infiltration into the outer coat, accompanied by endarteritis and periarteritis. The infiltration then extends along the vessels into the media, branching out in places into irregular cellular areas in which there is also new formation of thin-walled vessels. In some cases necrosis of the media ensues. This leads to absorption of the muscular and elastic tissues of the media, and sections stained to show the elastic tissue present breaks, or "windows," corresponding to the cellular areas, which may extend across even the full extent of the media. At a later period new formation of connective tissue takes place, with resultant fibrous patches in the media, wholly devoid of muscle and elastic tissue. This scar tissue is weak, and localized depressions or pouches, the potential predecessors of aneurysm, are often visible on the intimal aspect.

If the aorta is affected immediately above the valve the aortic cusps may be affected, so producing valvular disease. The orifices of the coronary arteries, too, may become involved, with narrowing, or even complete occlusion, of the lumen. Occasionally a plaque may form on the mitral valve, but it is usually small, and syphilis plays an insignificant part in the production of chronic mitral disease.

Aneurysm.

The essential cause of aneurysm is weakness of the arterial wall, which gives way before the pressure of the blood within the vessel; this weakness mainly affects the media. Medial weakness may arise in different ways. It is most commonly due to syphilis, but a comparable lesion may occur from an acute infection—for instance in phthisis—if an ulcerative process happens to hit an artery; or in ulceration of the stomach. Thus fatal gastric haemorrhage may arise from the rupture of an aneurysm of the splenic artery, which has become involved in a chronic ulcer of the stomach. The media may also be affected from within in acute aortitis secondary to acute endocarditis or sepsis elsewhere. It may be damaged by the pressure of an atheromatous patch to

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Manchester, 1929.

a degree that permits dilatation; trauma may be an occasional cause. But aneurysm is most commonly of syphilitic origin.

Chronic Aortic Valvular Disease.

There is considerable difficulty in determining the precise causes of chronic valvular disease. More than one cause is often active; the chronicity of the disease prevents accurate observation of its progress, and the effects of different causes are similar, the ultimate result depending upon the site of the lesion rather than on the nature of the cause. In each case the cause has usually to be deduced from the history of the development of the symptoms, the antecedent illnesses, and the associated lesions in the aorta and elsewhere, rather than from the actual lesions which are found to be present.

Varied lesions are found at the post-mortem examination. The cusps are thickened, hardened, and opaque, the change being sometimes uniformly distributed throughout them, and sometimes confined to, or most extreme at, the free margins. Calcareous and atheromatous deposits are not uncommon, and, though usually merely an addition to a general lesion, are sometimes an isolated lesion in a fairly normal cusp. The calcareous masses may be large, and from their bulk interfere with the proper action of the valve.

The cusps may be shortened, or adherent to each other. Shortening produces incompetence, and adhesion narrowing, of the orifice; the two conditions frequently coexist. The ultimate result varies. The cusps may be more or less uniformly adherent, forming a funnel or dome or diaphragm. The orifice may be greatly narrowed, and rounded, linear, or stellate. Not infrequently warty outgrowths of varying size and consistence occur near the free margins. In other cases there is loss of substance, and the edges are puckered and uneven. The line of attachment of a cusp may be destroyed, and a part of it may be freely mobile in the blood stream, or, if calcified, project stiffly into the lumen.

A cusp may be perforated through its substance. This is most commonly the sequel of acute endocarditis, but, rarely, it follows severe muscular exertion or an external trauma, and then usually in a valve which has already been damaged. In the majority of chronic lesions the edges of the cusps are inverted to some extent. In exceptional cases the cusps are voluminous and soft, with everted edges, thus producing gross incompetence of the valve.

Chronic valvular disease may be of congenital origin, or it may follow acute endocarditis, a syphilitic infection, or mechanical strain; it may be merely an incident in a general cardio-vascular degeneration. Aortic valves with thick uneven edges and adhesion of the cusps, those which present scars in the immediate vicinity of the valve, whether in the aorta or the adjacent endocardium, and those accompanied by chronic disease of the mitral valve, are most frequently the result of acute endocarditis, usually of rheumatic origin. Cases which present syphilitic masses or scars on the proximal parts of the aorta, with comparable lesions on the aortic valves, are evidently specific in origin. But in many cases atheromatous disease is also present, and the exact origin of the valvular lesion is, in consequence, difficult to determine.

Atheroma.

Atheroma is by far the most common affection of the vascular tree. It affects arteries of all sizes, from the smallest to the largest, and is most common in the first part of the aorta, the coronary arteries, the cerebral arteries, and those of the limbs. The lesions may be widespread or localized to some particular set of vessels. A chronic affection of the aortic valve, with thickening and induration, often coexists, from a spread on to the valve of the same process that has affected the arteries.

The causes of atheroma are numerous. It is most common in persons of advanced years, representing the scars and bruises of ancient wars and the defective nutrition of a failing organism. In some instances the special localization points to stress or strain as causal, at any rate in part; in others, toxic influences or metabolic disturbances seem to have been active. In the majority of cases many or all of these factors have been active in the past. Atheroma is especially frequent in cases of chronic renal disease, with a high blood pressure and thickened arteries. If, in addition, a rheumatic or a syphilitic infection has been antecedent, the causes of the ultimate disease must of necessity be obscure. The exact influence of each can only be determined by the survey of a large series of cases.

Myocardial Disease.

There are several specific myocardial lesions, but in the majority of cases the myocardial lesions are only side issues, the result of coronary disease, and so in no way specific. The typical specific lesion is the gumma, but its occurrence is rare, and none is recorded in our series. Gummata vary in size from microscopic lesions to tumours as large as a pigeon's egg. They may be single or multiple; they may occur anywhere; and may occasion disturbances of the cardiac rhythm if they involve the primitive tissues. A diffuse fibrosis (subacute interstitial fibrosis) has been found during the secondary stages in the adult, and, more often, in congenital syphilis in infants and young children.

The most important, and the most frequent, sequel of syphilis follows disease of the coronary arteries and interference with the blood supply of the muscle. The arteries may be occluded at their orifice by a syphilitic plaque in the aorta, or narrowed in their course by a specific endarteritis. If the circulation is completely blocked an infarct occurs, while if the narrowing is incomplete a para-arterial fibrosis results. The ultimate lesions in the muscle are not syphilitic, though they have a syphilitic cause.

Pericarditis.

The influence of syphilis as a cause of pericarditis is negligible. Pericarditis may, of course, occur in relation to a gumma of the heart or a diffuse syphilitic fibrosis. Syphilis seems sometimes to be the cause of indurative mediastino-pericarditis, the inflammation usually arising beneath the diaphragm, about the liver, and spreading upwards. But the few cases of syphilitic pericarditis which have been reported are unconvincing, and can be neglected.

THE CLINICAL DATA.

Aortitis.

Aortitis may occur in any acute infection, but it is rare save in acute endocarditis, particularly of the aortic valve. The infection may be conveyed directly, by continuity or through the aortic blood, or through the vasa in the adventitia. The most common organisms are streptococci; but any pathogenic bacteria may be active. It occurs not infrequently in acute rheumatism and rarely in tuberculosis, but the lesions in these diseases are usually limited in their extent and not excessive in degree.

The chief cause of aortitis is undoubtedly syphilis. It is difficult to say when the lesions arise, but it seems probable that they may occur early, in untreated cases even in the secondary stages, though they are rarely recognized until many years have passed. The reason of this failure to recognize its presence is clear. Aortitis *per se* does not occasion any symptoms. These only arise if "something happens"—an aneurysm forming, or the aortic cusps or the orifices of the coronary arteries becoming implicated in the syphilitic process. Aortitis is thus most commonly a post-mortem discovery. It was present in 59 of the 60 syphilitic cases in the post-mortem series. Of these, 29 died from lesions in the heart and aorta, the remaining 30 from other causes, the most frequent of which were cerebral.

In this form of syphilitic disease it is impossible to ascribe particular symptoms to particular lesions, for aneurysm, aortic valvular disease, and obstruction of the coronary arteries are all almost always present in some degree in every case. The degree, of course, varies. The "aneurysm" may be a mere pouching of the aortic wall, or a sac as large as a baby's head. The damage to the cusps may be trifling or extreme. The coronary narrowing may be slight or complete.

None of these lesions necessarily produce symptoms. One of our patients with a large aneurysm and well-marked aortic valvular disease had no cardiac symptoms. He was

admitted into hospital on account of a chill, which followed a very gallant and successful attempt to save a comrade who had fallen overboard in wintry weather. He had carried on his work easily and well. Another patient, a labourer, was admitted on account of the thrombosis of a popliteal aneurysm. He had well-marked aortic valvular disease, which had never inconvenienced him. A padre, who had had an infarct of his heart in 1920, carried on his work, easily and well, for more than five years after his convalescence, and even took on fresh responsibilities, though on his death in 1928 a large area of fibrosis was found to be present on the posterior wall of the left ventricle and the adjacent septum.

The symptoms of syphilitic heart disease do not differ from those of similar disease due to other causes. But although the symptoms of rheumatic and syphilitic disease are essentially similar there are some features peculiar to each. The dyspnœa of rheumatic disease is most often associated with exertion, while that of the syphilitic form often occurs in paroxysms at night, when the patient is in bed. One of our patients, who admitted that he had been becoming more short of breath on exertion for a few months, but had paid no attention to his discomforts, was forced to seek help when, without warning, he was wakened from sleep by paroxysms of intense breathlessness. Pain, too, may be of this paroxysmal character, and occur at night, without warning. These paroxysmal attacks are, of course, due to coronary obstruction, which is much more rare in the rheumatic disease.

Continued pain is sometimes due to aneurysm. In rheumatic disease continued pain is usually due to pericarditis or infarctions. The palpitation of rheumatic disease is generally due to an alteration of the cardiac rhythm, extra-systoles, fibrillation, etc., while in syphilitic disease it is usually the result of gross incompetence of the aortic valve and the throbbing of the arteries. If the aorta is dilated the palpitation may be referred to the base of the heart rather than to the cardiac area generally. Œdema in rheumatic disease is of gravity distribution, while in syphilis it may be local, from pressure of an aneurysm upon a vein. Complaint of constriction, oppression, or discomfort over the manubrium on exertion is suggestive of aortitis.

The appearance of the patient may be instructive. The rheumatic patient may be cyanosed, or, occasionally, pale, if an acute endocarditis has supervened. The syphilitic patient is often thin and emaciated, and perhaps of sallow, earthy complexion. Physical signs are sometimes suggestive. Not infrequently pulsation, from some slight dilatation of the vessels, is well marked over the upper part of the chest, above the sternum, or above the clavicle. A systolic aortic murmur sometimes precedes the advent of the diastolic murmur, though stenosis of the orifice is rare. The second aortic sound may be accentuated, though the blood pressure is not high, and may be intoned or ringing in character. The *x*-ray picture may show enlargement of the aortic shadow, even in minor dilatations, the normal outlines of the heart and aorta being lost.

The association of syphilis with aneurysm has long been recognized (Ambroise Paré[6]), but was forgotten by most writers until, in the latter half of last century, the connexion was again stressed by our army surgeons (Lewer,[7] Lawson,[8] Welch[9]), and in 1909[10] spirochætes were demonstrated in syphilitic aortitis. Further researches, using the Wassermann test, have emphasized the frequency of the connexion In our series of 66 cases of chronic aneurysm, 49 (74.2 per cent.) were syphilitic.

The incidence of aneurysm points the same moral. It is most common in men between 40 and 60, the age when syphilitic disease of the heart is most frequent; our youngest patient was aged 26. Usually the condition occurs ten to twenty years after the primary infection, but it has been reported during the secondary stages (Lewer, ten months after the chancre), and in one of Osler's cerebral cases eighteen months after infection.

Chronic Aortic Valvular Disease.

Syphilis is an important etiological factor in chronic aortic valvular disease. In a clinical series of 224 cases it was apparently causal in nearly a third of the cases. The incidence in men and women, however, differs, as it occurred in rather more than a third of the men, and rather less than a fifth of the women. The age incidence is important. Nearly half of the cases in the forties and the fifties were due to syphilis, while only one case occurred under 30, and less than a quarter of the patients over 60 were syphilitic. In the post-mortem series of 145 cases rather less than a fifth of the cases were syphilitic. Nearly a fourth of the patients in the forties and fifties were syphilitic, while after 60 the incidence diminished to less than an eleventh.

It is interesting to note that in the clinical series the incidence of syphilis and rheumatism is approximately the same—32.1 and 33.9 per cent. The age and the sex incidence, however, differ. Less than a third of the men and more than a half of the women were rheumatic, and nearly a third of these patients were under 30 years old. The occurrence of aortic valvular disease in the forties or the fifties, especialy in men, without a clear history of antecedent rheumatism, is thus very suggestive of a specific origin of the lesion.

The physical signs of aortic valvular disease are merely the signs of the valvular lesion, irrespective of its origin. It has been suggested that the absence of the second aortic sound suggests syphilis rather than rheumatism. It is quite true that the second sound usually persists in the rheumatic group; it is often accentuated, and frequently intoned in the degenerative cases, as one would expect from the nature of the lesions. Too much attention, however, must not be paid to this point, as it is really more an index of the degree of the lesion than a suggestion of its cause; but attention should be paid to the second pulmonary sound.

In syphilitic disease of the aortic valve the mitral valve is rarely affected, while in the rheumatic disease the mitral valve is affected in the majority of cases. In a clinical series of 51 syphilitic cases the aortic valve was alone involved in 31 cases; and in a series of 146 cases of acute endocarditis in 18 cases alone. The post-mortem series are equally striking. The mitral valve was only affected in one of 27 syphilitic cases, but in 45—more than 25 per cent.—of 163 cases in the non-syphilitic group. In mitral disease the second pulmonary sound is usually accentuated, and its presence thus suggests coincident mitral disease, and so a rheumatic origin of the double lesion.

Aortic aneurysm and dilatation of the aorta are usually due to syphilis. Widespread pulsation over the upper part of the chest, pulsation in the suprasternal notch, and dilated carotid arteries thus suggest a syphilitic cause. In some cases an abnormal distribution of the murmurs, beyond the cardiac area, points to a dilatation of the aorta which has not yet shown itself by the signs which we have just mentioned. All these data, however, may be absent, and the diagnosis will depend upon the recognition of a specific infection in the past, a positive Wassermann reaction, or syphilitic stigmata elsewhere.

Chronic Mitral Valvular Disease.

Mitral valvular disease is rarely due to syphilis. In a clinical series of 102 cases of chronic mitral disease only two patients were known to be syphilitic, and in another series of 121 cases only one patient. In the post-mortem series only one of the 60 syphilitic patients had mitral disease, in this case coincident with aortic disease. In the non-syphilitic group (330 cases) there were 55 cases of coincident mitral and aortic disease, as well as 32 cases in which the mitral valve alone was affected.

The incidence of acute endocarditis, too, differs. Only 5 of the 27 syphilitic aortic cases were accompanied by acute endocarditis; while 35 of the 55 cases of aortic and mitral disease, and 16 of the 32 purely mitral cases, presented some degree of acute endocarditis at necropsy. It is, of course, well known that patients suffering from a chronic rheumatic endocarditis frequently develop an acute reinfection of the valve affected.

The sex and age incidence of aortic and mitral disease differ. In the clinical series of aortic disease 173 were male and 51 female. In the post-mortem series 112 were male and 41 female. The combined aortic and mitral series show 31 males and 24 females. The pure mitral

cases show 14 males and 18 females. In the clinical aortic series 63 of 224 cases occurred before the age of 40, and in the post-mortem series 15 of 153 cases. In the mitral group 13 of the 32 cases, and in the combined group 23 of the 55 cases, occurred before this age.

Myocardial Disease.

We have tried to estimate the relative frequency of syphilitic disease of the myocardium by examination of our data. The clinical series, however, affords little information, for the majority of the patients were unable to give a full account of their past illnesses or, indeed, to permit a complete examination. But it is interesting to note that *the maximal incidence occurred in the fifties and the sixties*, a decade later than the maximal incidence of the syphilitic group in the post-mortem series. In the latter series disease of the coronary arteries was more frequent in the syphilitic cases (23.3 per cent.) than in the non-syphilitic cases (15.7 per cent.). The incidence of fibrosis in the two groups, however, is but little different (50 per cent. and 57 per cent.), which suggests that the degree of the arterial lesions is of more importance than its cause.

The incidence of fibrosis, with and without coronary disease, is greater in the non-syphilitic (21.2 per cent.) *than in the syphilitic group (16.6 per cent.). This is* probably due to the frequency of valvular disease in the non-coronary cases (16 of 40), and the resulting myocarditis.

We have been unable to discover any symptoms which are suggestive of a specific origin of myocardial disease; but the occurrence of symptoms of myocardial weakness without obvious cause should at once suggest the possibility of a syphilitic origin, particularly if the patient has not reached the age of 60. The majority of the patients suffering from gumma of the heart seem to have been "admitted dead" into hospital.[11]

Angina Pectoris.

The connexion between syphilis and angina has been stressed by many writers, but the exact relationship has not yet been determined, as the cause of angina is still disputed. The current theory, a revival of one first suggested by Allan Burns[12] in 1809, has been elaborated from the experimental side by J. A. MacWilliam[13] in 1923, and from the clinical side by C. S. Keefer and W. H. Resnik[14] in 1928. According to this theory angina is due to anoxaemia of the heart muscle, most commonly as the result of disease of the coronary arteries. The conception is physiological, not anatomical—a relative insufficiency of the blood supply of the heart, taking into account the work which the heart is accomplishing at the moment.

We cannot find many statistics as to the incidence of syphilis in angina. Huchard[15] recognized a syphilitic taint in 170 of 740 cases, and Josue[16] found a positive Wassermann reaction in 33 per cent. of his patients. Heimann[17] noted that 68 of his 105 cases of cardio-vascular syphilis made a complaint of pain, and in 44 pain was the cardinal symptom. In 3 of 7 cases in which we secured a post-mortem examination a syphilitic aortitis was present.

Angina is most common between the ages of 50 and 70. This is a decade later than the common age of aortitis as shown post mortem. But, although it is uncommon before 30, it may occur earlier, as in Wild's patient aged 12, in Moxon's patient aged 11, and in Daniélopolu's syphilitic patient aged 20.[18] There does not seem to be any special symptom suggestive of a syphilitic origin. The occurrence of angina before the age of 40, and its association with aortic valvular disease, should suggest a syphilitic cause, and an investigation into the possibility of a syphilitic origin should be made.

DIAGNOSIS.

The chief causes of heart disease are rheumatism, syphilis, bacterial endocarditis, and the degenerative lesions, of which atheroma is the type. It is difficult to say which is the most important, as their activities are maximal at different periods of life. Rheumatism is most important in early life, the degenerative lesions towards its close. Bacterial endocarditis accompanies rheumatism, while syphilis enters the stage at the very prime of life. Their actions, too, differ. Rheumatism and bacterial endocarditis attack the valves and the pericardium. Degenerative lesions attack the valves and the arteries, and syphilis follows suit. The diagnosis of syphilitic disease of the heart depends upon the recognition that syphilis is an important cause of heart disease.

In a general way syphilitic heart disease occurs in the later phases of the illness, when the primary illness has been almost forgotten and specific symptoms are absent. It is most frequent in the forties and the fifties, and in men as contrasted with women. The symptoms it causes are those of the cardiac lesion, and not those of syphilis. Aortitis and aneurysm are so frequently due to syphilis that their mere recognition suggests the cause. Of the valvular lesions mitral disease is so seldom associated with syphilis that its influence can be ignored. Aortic valvular disease, on the other hand, is frequently due to syphilis, whose influence should always be investigated. Myocardial disease and angina pectoris are often the result of syphilis, but less frequently than aortic valvular disease. Pericarditis is rarely due to syphilis.

The personal and the family history are important, but these are not always accurate. One must remember that the primary manifestations are sometimes trivial and unrecognized, even when suspected. The error may be due *to the patient or to his medical adviser.* A positive Wassermann reaction is important, for although the test is not specific in the serological sense, it is rarely obtained in this country save in syphilitic cases. A negative result has not the same significance, for the reaction is *only* positive in about 75 per cent. of patients in the tertiary stage, the period at which most syphilitic cardiac patients come under observation. We have all, we imagine, seen good results follow specific treatment in patients whose Wassermann reaction has been frankly negative.

A full routine examination may discover signs of diagnostic significance elsewhere than in the heart. Scars on the penis, the throat, or the shins, nodes on the bones, loss of the deep reflexes or the light response in the eyes, leucoplakia, orchitis, unequal pupils, iritis, choroiditis, periphlebitis of the retinal vessels, optic atrophy, or the early symptoms of tabes or general paralysis of the insane, if present, may be decisive.

TREATMENT.

In the treatment of cardiac syphilis the two sides of the question—the constitutional and the local—must be borne in mind. From the cardiac side the treatment is the same as in the non-syphilitic varieties. From the constitutional side specific treatment is required as urgently as in syphilitic disease elsewhere. Too much, however, must not be expected from such medication, for the lesions, when recognized, are as a rule in an advanced stage.

The most common lesion is endarteritis, which is often accompanied by thrombosis. But the latter, as Gowers pointed out many years ago, is not a specific process, and is not amenable to specific treatment. The necrotic tissue cannot be revived; but at its periphery the tissues are linked up with other arterial territories, and if, by specific treatment, the lumen of their arteries can be enlarged the nutrition of the tissues, starved but not killed by the cessation of the blood supply from the thrombosed vessel, will be increased, and their functional activity correspondingly increased.

Syphilitic lesions may be "active" many years after the initial infection. One of our patients, who died at the age of 50, had contracted the disease thirty-three years before. The aorta, which presented syphilitic scars over most of its thoracic course, showed one small typical "active" nodule.

The nature of the specific treatment requires consideration. Should a "sterilizing" treatment be attempted or a milder course pursued? Are the arsenical preparations advisable, or mercury and iodide? It is obviously inadvisable to administer full doses of salvarsan to a man *racked with pain or distressed with orthopnoea. Renal disease, which is so often present, is another contra-*indication, and, of course, massive oedema; but is it inadvisable in the case of a strong man whose disability has been discovered in the course of some routine examination, in whom no symptoms of cardiac difficulty obtain, or in those whose disabilities are slight?

Those of us who had to deal with malaria during the late war found a similar difficulty before us. But it was soon apparent to us all that, although we could treat primary malaria successfully by massive doses of quinine, such treatment was useless, if not harmful, in the chronic infections. Smaller doses were more efficacious. Syphilitic heart disease is of the chronic type.

Another consideration should also be borne in mind. It is well known that the administration of tuberculin in large doses to a patient suffering from phthisis may produce both a general reaction *and* a local one at the site of the focus. A similar reaction may occur in syphilis if large doses of the arsenical preparations are administered (Jarisch-Herxheimer reaction).[19] The general opinion is that this is due to the sudden liberation of toxins from the bodies of the organisms that are destroyed. But, whatever the cause, it is obviously hazardous to expose a patient with, possibly, a narrowed coronary orifice to the danger of a local reaction and the complete obstruction of the artery. If arsenic is used in such cases it should only be subsequent to a course of mercury and iodide, and in moderate doses.

We have thus continued to treat cases of cardiac syphilis along the usual lines, with moderate doses of mercury and iodide, etc., over long periods of time. Small doses of kharsivan, or neokharsivan, are sometimes useful, as are Donovan's solution, the green iodide of mercury, arsenic iodide, and potassium iodide. The results which we have observed have sometimes been extremely satisfactory. We must always remember, however, that *the true treatment of cardiac syphilis is preventive*, the successful treatment of the primary illness, and that cardiac syphilis is the result of error, on the part of the patient or his medical adviser.

THE DIAGNOSIS OF FRONTAL TUMOURS.*

BY

JAMES COLLIER, M.D., F.R.C.P.,

CONSULTING PHYSICIAN AND EMERITUS LECTURER ON NEUROLOGY, ST. GEORGE'S HOSPITAL, LONDON.

FROM the very nature of the cerebral hemispheres the regional diagnosis of disease situated therein is often a matter of peculiar difficulty. The cerebral hemispheres have their origin as appendages to the nervous mechanism subserving the olfactory sense, and have doubtless acquired dominance in the nervous system from the importance of the sense of smell in acquiring food and scenting danger, and so providing for the survival and advance of the race.

The cerebral hemispheres have no primary and direct connexions with any other function than that of smell, nor with any other region than the olfactory region. Secondary connexions are developed, as evolution proceeds, by mediate paths with every function and with every region of the body; and in the higher vertebrates the cerebral hemispheres become increasingly and more directly linked up with specific bodily functions, by the development of certain great white tracts which directly impinge upon, or take their origin from, the cerebral cortex. Interference with the integrity of these white tracts produces definite and recognizable clinical signs. Even in man there are not many of these paths. There is the visual path entering the cortex of the cuneus and posterior pole. There is the auditory path to the temporal regions, the higher sensory path to the parietal lobes, and paths subserving incoming and outgoing speech connected with the left temporal lobe. With the knowledge of the anatomical details of these paths and of the results of lesions interrupting them, our knowledge of cerebral localization of function begins and ends. It is only because quick and easy compensation does not occur for lesions of these paths in man that we have even this slight knowledge of cerebral localization. In vertebrates lower than man such compensation occurs readily. Sherrington removed successively the right and left motor cortex from a chimpanzee. The animal recovered his motility perfectly. And when long recovered and a normal chimpanzee, an investigation was made to find where the motor cortex had been transferred to, and it was found that there was no excitable cortex—that there was no motor area in this perfect animal. No local motor function of the cortex had been abrogated by the destruction of the motor cortex. Only the pyramidal path had been destroyed, and Nature had found another way out for the exteriorization of motor function.

Hughlings Jackson, in the Croonian Lectures for 1884, formulated a theory of the way in which the nervous system worked. It has long since been proved to be anatomically acceptable by Golgi and his followers, who built up the "neurone" concept. It seems to be increasingly acceptable, physiologically and clinically, as time goes on. That part of Jackson's theory which concerns us on this subject may be put in two sentences. There are several structural and functional levels in the nervous system from the lowest to the highest. In the lowest level, which is represented by the spinal segment, simple structure and simple function are directly represented, but with each higher level everything below is re-represented in increasing compound proportion, so that in the highest level there can be no local representation, but a representation of some attribute of the physiological individual as a whole. Hughlings Jackson—so often on the lips of neurologists, so little read and so ill understood—is often called the "father of cortical localization," for his theory preceded Hitzig's experimental work; he was, in fact, the destroyer of cortical localization in that his theory is directly antagonistic to local residence of function in the highest part of the nervous system. Therefore, in considering what may be the signs of tumours within the frontal lobe, if we are to advance in knowledge we must divest our minds of any idea of local function, mental or other, peculiar to lesions of the prefrontal lobes; we must expect a varying clinical picture, and often one which is negative so far as localizing symptoms are concerned. We must bear in mind the great facility for compensation for local lesions within this region so fully emphasized by Gowers forty years ago, and keep in mind the disturbing effects of long-standing increase of intracranial pressure and of hydrocephalus upon the value of those signs which we use for localization, and strive to make a collect of those signs which have been useful to us collectively in the successful localization of tumours within the frontal lobe, for we do locate them successfully very often. I may conveniently divide the signs which are used for the location of a tumour within the prefrontal lobes into five categories:

1. The negative signs.
2. The contiguous signs.
3. The signs which have been deemed peculiar to, or especially marked in, prefrontal lesions.
4. The signs peculiar to lesions within the anterior fossa of the skull.
5. The signs revealed by ventriculography.

Negative Signs.

The negative signs are of especial importance, since tumours within the posterior fossa below the tentorium, and those of the occipital, parietal, central, and left temporal regions, except sometimes in their latest stages, give unmistakable signs of their position. Therefore if there be no definite localizing sign, it is commonly a matter of a

* A paper read in opening a discussion in the Section of Neurology and Psychological Medicine at the Annual Meeting of the British Medical Association, Manchester, 1929.

prefrontal or a right temporal site. It is only when a subtentorial tumour has given rise to hydrocephalus that we are likely to choose a frontal location from the mental reduction therewith associated—recently under my observation a [illegible] t larger than an inch of slate pencil, the length of the aqueduct of Sylvius and not itself producing any local signs, gave rise to hydrocephalus and secondary dyspituitarism closely simulating a suprasellar tumour—or when the long-raised pressure from a frontal tumour has shifted the brain stem backwards and pushed some of the cerebellum into the spinal canal and so caused paralysis of cranial nerves and cerebellar signs.

The Contiguous Signs.

The contiguous signs are those produced by the extension of some process connected with the growth—either pressure, oedema, or vascular disturbance—into the neighbouring ascending frontal convolution giving rise to motor weakness, or into the insula of the left side giving rise to interference with the execution of language, or into the paths converging to the forward part of the corpus callosum and so producing motor apraxia. The motor weakness is seen first and most in the face, rarely in the arm, and almost never in the leg. It is perhaps the most important lateralizing sign of a frontal tumour, but it does not distinguish a frontal tumour from a temporal tumour, which also frequently causes weakness of the face as a contiguous sign. When the facial weakness is obviously greater for emotional movement than for volitional the location should be a temporal one.

Difficulty in the exteriorization of language is a certain lateralizing sign of a left hemisphere lesion in a right-handed person, but it is also caused by tumours of the left insula and those of the anterior temporal region. It should be of the nature of a stammering defect or of a "pure aphasia" if due to a frontal lesion. The presence of any lack of speech acceptance or any difficulty of recall demands a location far back in the temporal lobe. Pure executive apraxia seems to be a certain sign of prefrontal involvement and to lateralize to the left side. Presumably it indicates a lesion extending deeply and far back in the upper two prefrontal convolutions. It can hardly be confused with agnostic or ideational apraxia, which results from a lesion further back in the hemisphere. Unfortunately it is of uncommon occurrence with prefrontal tumours.

Lesions Peculiar to the Frontal Lobe.

I will now proceed to a consideration of those signs which have been held to be peculiar to lesions of the frontal lobe, or to be especially marked as the result of such lesions.

Mental Symptoms.—We shall, I am sure, all agree that mental changes of a very variable order, from slight changes in the way of loss of reserve, childishness, and change of character, to severe disturbance such as megalomania, "witzelsucht," and amentia, do result from tumours of the prefrontal region. I will ask you whether you agree with Cushing's very confident statement that mental changes are always much more conspicuous in left-sided lesions, for I am doubtful as to this point. On the other hand, we all know well that most extensive lesions of the frontal lobe often exist without any obvious mental change. The explanation seems to be the possibility of compensation, and whether the other frontal lobe is relatively intact as regards its callosal connexions, since bilateral frontal lesions always give rise, both experimentally and clinically, to marked mental reduction. The point of importance is whether mental changes are of sufficiently higher incidence with prefrontal lesions, as compared with lesions of other regions of the brain, as to make them reliable symptoms when other localizing symptoms are absent. "Seelenlahmung," or "soul paralysis," "witzelsucht," and "mind blindness," were all originally described as resulting from lesions of the posterior part of the hemisphere. The most dramatic mental changes that I have ever seen resulting from cerebral tumour occurred with tumours of the temporal lobe, the outer surface of the occipital lobe, and the splenium of the corpus callosum respectively. I wish especially to emphasize the early loss of memory and the mental reduction occurring in tumours of the splenium callosi, because it may be the key to the explanation of mental changes and their variability in cases of cerebral tumour. I have in six cases made a correct regional diagnosis in the splenium callosi on the mental symptoms alone. Bristowe, many years ago, published four cases so alike as to enable him to make an accurate regional diagnosis in the last three of them. Giese and Bruns confirmed Bristowe's opinion, and Ferrier made an analysis of sixteen recorded cases and agreed with his clinical findings.

The lesion of the splenium callosi interrupts many of the connecting paths between the various regions of the hemispheres, and thereby, I submit, causes disorientation and mental changes. The isolated lesions of the brain which have been recorded as productive of "seelenlahmung," "witzelsucht," "mind blindness," and the apraxias have on my analysis always been lesions extending deeply into the white matter, and presumably freely interrupting transcortical paths, and I submit that it is the isolation of the various parts of the cortex from one another which is the chief cause of mental impairment rather than damage to the cortex itself. In Shilder's disease, for example, when the lesion is of the central white matter with the cortex intact, the mental change is very great. Therefore, in lesions of the prefrontal lobe, I suggest that mental changes are only conspicuous when the tumour extends deeply and cuts the callosal and other transcortical paths.

Frontal tremors, most marked upon the homolateral side and sometimes confined to that side, were first described by Grainger Stewart in 1906. Like other signs described at first as proper to the prefrontal lobe it has come to belong also to the temporal lobe, for Schwab in 1925, in 6 cases of temporal tumour, describes it as contralateral and of great lateralizing value. Kolodny, working under Gordon Holmes at Queen Square, describes it in 14 out of 38 cases of temporal tumour. In 4 cases it was homolateral, in 7 cases contralateral, and in 3 cases bilateral. He concludes that this tremor is not of lateralizing value, and that it will not distinguish frontal tumours from temporal tumours. Collins records an identical tremor in tumours of the post-central region. Recently, when called to a case of cerebral tumour in which the general symptoms were very urgent, these tremors were conspicuous in the left hand and foot, and they were the only localizing signs which I could find. Consequently an operation for left frontal tumour was carried out. On laying bare the bone for a very wide decompression a dark patch was seen in the posterior inferior temporal region, and this led to the completely successful removal of an endothelium buried in the back of the left temporal. How this tumour could have existed in such a situation in a right-handed subject without trace of speech defect or hemianopia, either before or after the operation, is a matter worthy of reflection. In this case Stewart's tremors were of certain lateralizing value, and the patient's life was saved thereby, though the location was wrong.

The "*grasping and groping*" reflex of Adie and Critchley is, as far as I know, a certain sign of prefrontal location which has not yet been seen with lesions elsewhere. Gordon Holmes thinks it is seen with very extensive frontal lesions, but I disagree with this opinion. Critchley associates it with lesions high up and far back in the prefrontal region.

Conjugate deviation of head and eyes, or of eyes alone, to the contralateral side, explained by an involvement of the frontal ocular area said to occupy Exner's region in the second frontal gyrus, has been repeatedly emphasized as of locating and lateralizing value, and recently by Gordon Holmes. Now I have seen Schafer's experiment producing conjugate deviation by stimulation of the occipital cortex. I know well of Ferrier's equally striking and similar result from stimulation of the parietal cortex, as well as Foerster's result from the temporal cortex, and everyone's result from the central cortex, and it seems to me certain that every cortical region must of necessity be an origin for incitations for conjugate deviation, considering the necessary association in life of conjugate deviation with every movement and sensation, and therefore conjugate deviation cannot be in any way special to the prefrontal lobes; nor do I believe that there is any special region

for this function. I have recently had under my care two patients with extreme and persistent conjugate deviation of head and eyes lasting for weeks. In one case a large glioma almost completely excavating the left frontal lobe, but not involving the cortex, was found. In the second case, in which the lesion was right-sided, the presence of complete hemianopia and astereognosis with marked hemianalgesia and very little hemiplegia made it certain that the lesion was in the posterior half of the hemisphere. I may, however, go so far as to say that conjugate deviation, when persisting in the absence of other localizing signs, may indicate either a frontal or a temporal location, but it will not distinguish between the two, for Kolodny found it well marked in 6 out of 38 cases of temporal tumour. When present it is of certain lateralizing value for tumours in any part of the hemisphere. It may be seen in the form of persistent deviation to the contralateral side, or of weakness and unwillingness in deviation to the ipsolateral side.

Loss or diminution of the trunk reflexes may be of great lateralizing value, and is said to be valuable in frontal location. But I hold that it is much more characteristic of the temporal tumour, and I have several times located a temporal tumour and had it successfully removed when this was the only localizing sign present. In one-half of Kolodny's temporal cases the trunk reflexes were completely absent on the contralateral side. The presence of these reflexes has no negating significance. In both frontal and temporal tumours it is probably a contiguous sign of pressure upon the pyramidal mechanism.

Incontinence is sometimes very marked in frontal tumours, even when the mental aberration is inconspicuous. I think I have seen it more often in temporal tumours. It was present in 20 per cent. of Kolodny's cases of temporal tumours.

Papilloedema was said by Leslie Paton to occur earlier and more severely with tumours of the hemisphere the farther forward these were situated. Recently Stopford has analysed another series of cases, and comes to the conclusion that the farther back the situation the earlier and more intense the papilloedema. I am inclined to agree with Stopford, though I do not think papilloedema is of any value, either in localization or in lateralization. Horsley affirmed that it was greater on the side of the tumour. With frontal tumours one might reasonably expect it to be less on the side of the tumour, since major local pressure at the back of the orbit tends to delay the onset of papilloedema. I have seen a good many very large frontal tumours come to autopsy without having developed papilloedema.

Lethargy of a deep but rousable kind has occurred many times in frontal tumour, and when existing without headache or papilloedema it has caused several cases at the National Hospital to reach the post-mortem room with the label "lethargic encephalitis." One patient came under my care with deep lethargy following immediately upon an attack of influenza. I cured this patient at St. George's Hospital with injections of collosol iodine and salicylates, and she remained quite well and at work until fifteen months later, when a second attack of lethargy proved fatal, and I found a very large right-sided frontal tumour. This patient had no headache and never developed papilloedema. I am well aware of lethargy as occurring with pineal tumours and tumours of the upper brain stem, but I have only seen lethargy of this nature in tumours of the frontal region so far as the hemispheres are concerned.

Fits of many kinds occur with frontal tumours. I have seen characteristic minor attacks occurring frequently as the sole epileptic manifestation. Hughlings Jackson spoke of convulsions with bilateral commencement as indications of frontal location, but perhaps this was more from theoretical considerations than from practical experience. The convulsions I have seen have always commenced with conjugate deviation, which deviation has been a sure lateralizing sign. Status epilepticus is an interesting frontal symptom. I have records of two cases which were in hospital under treatment for fits, and in which no signs of local lesion of the nervous system were found. These patients developed status epilepticus and perished, and in both cases a frontal tumour was found. I have no knowledge of any other region of the brain in which a tumour has produced status epilepticus.

There remain for consideration certain phenomena, such as Mayer's reflex, Leri's reflex, and Hoffman's reflex, which are said to be absent in prefrontal lesions, and Wessenberg's sign, which is supposed to be found only when a prefrontal lesion is present. Of these signs I have not much experience.

Signs Peculiar to Lesions of the Anterior Fossa.

The signs peculiar to the anterior fossa of the skull are those of pressure upon the olfactory tract, the optic nerve or chiasma, or upon the nerves and vessels passing through the sphenoidal fissure, and those of bony involvement. These are always certain localizing and lateralizing signs, but they only obtain with a hard tumour coming to the surface of the orbital lobe or with a growth of meninges or bone.

Signs Revealed by Ventriculography.

There remains the method of ventriculography, which in skilled hands has resulted in many brilliant successes in this and in other difficult regions of the brain.

I hope that in introducing this subject to you I have said nothing that is dogmatic and nothing that is antagonistic to the feelings of any of you. If I have done so my fate will surely be that of all who are too sure about so delicate a subject as location within the cerebral hemispheres. May I tell you a story of one who did dogmatize? It concerns no less an observer and fine neurologist than Albert Knapp, who, in his monograph on *Tumours of the Temporal Lobe*, wrote: "Paralysis of the sixth nerve, so common in tumours of the hemispheres elsewhere, is practically unknown with temporal tumours, and its absence is of localizing value. I have myself recorded the only case in the literature of the subject." I am informed that after publishing this monograph the six consecutive cases of temporal tumour which came under Professor Knapp's care all had sixth nerve paralysis.

INCIDENCE OF DISEASE OF THE BLADDER IN WORKERS IN CERTAIN CHEMICALS.*

BY

THOS. H. WIGNALL, M.B., B.CH.,

APPOINTED SURGEON, HOME OFFICE, TO BRITISH DYESTUFFS CORPORATION, LTD.

I HAVE lived in the vicinity of a chemical works for nearly thirty years, and for the period 1900 to 1910 had, as patients, many men who had worked at this factory for several years. Since 1918 I have held the position of appointed surgeon for the factory, and have had, at all times, perfect freedom of access and much help from the managers and staff chemists in all problems that arose.

In the early periods (1860 and on) of the making of certain dyes from coal-tar products arsenic was largely used (As_2O_3); workers were not protected in any way, and cases of toxaemia were only beginning to be observed. At these times any man who offered himself got a job, if such were available. Cases were sent to the doctor simply as they happened, and no records were kept. No other system was thought necessary. Now we only take mature men below a certain age; they are examined as to indications of good health and evidences of skin trouble. A well-fitted first-aid station and a competent nurse are provided, and all cases are seen medically on the spot as soon as possible after report. Also, men are encouraged to report on any deviation from general health, and such cases are investigated, there being an attempt to promote good feeling always between doctor, nurse, and men, so no trivial report is ignored, and all cases are recorded. It is, however, not easy to give percentages of incidence of disease in chemical workers, because usually a man's job is not the same over a long period, and prior to coming

* Read in opening a discussion in the Section of Occupational Diseases at the Annual Meeting of the British Medical Association, Manchester, 1929.

to this factory he may have worked on pitch, tar, etc., or at a similar dye-making works. Chemical plants do not employ the same number of men constantly, and in the dyestuffs industry there may be such a large number of products chemically different that the works atmosphere is a mixture of various odours, and so, day after day, one inhales something from everything going on.

Again, quite a large percentage of the men employed are lead-burners, plumbers, joiners, mechanics, electricians, and other artisans, so that unless we had a steady number of men constantly on the same chemical process over many years, percentages would be of little value.

In a chemical work[illegible] one might expect men reporting, [illegible] of urine, because sometimes, in spite of muzzles, air-draughts, washing, etc., face, hands, tongue, and mouth are freely coloured, and ingestion, or perhaps absorption through the skin, occurs. This pigmentation of urine rarely happens, but we must impress upon men the necessity of reporting such changes. Of course, the object of this desire for a report from men is to see quite early any alteration of urinary colour in order to eliminate pathological pigmentation.

It is well known that reaction to dyestuffs varies with individuals, and with age and habits, blonds being more susceptible, and alcoholics also.

Primarily, certain chemical groups are known to cause forms of acute dermatitis and conjunctivitis, or bronchial and nasal troubles; others—for example, aniline—by absorption, ingestion, or inhalation, in acute cases produce illness, and pigmentation, visible on face, hands, and ears, as well as general bodily weakness, dyspnoea, and possibly blood in the urine, owing to the production of methaemoglobin in the blood. Such cases, seen early and treated, recover health, and I have not heard of any subsequent growths from acute illnesses of this type.

During 1919 a number of men working on a reduction process reported alteration in urinary colour, and some, not even feeling ill, were found passing blood in the urine; there were about 23 cases in all. This was traced to the effects of AsH_3. Many of the men were sent to hospital, and all recovered their health. After the war, and the change over to peace conditions, many of these men left the works, and their subsequent history is not known. The source of the arsenic was in the acid employed, and only pure acid afterwards was used. Lead-burners using hydrogen produced from impure acid containing arsenic were liable to be affected as the result of inhalation, and two cases were known. With improved conditions no further case of this type has been seen.

Quite a number of intermediates, as well as finished dyestuffs, can produce in some persons, varying with idiosyncrasies—for example, sweating, colour of hair and skin, seasons—extensive acute dermatitis, and this often recurs in the same individual if re-employed.

Although I have had many such cases, I have only met one case of surface epithelioma which might follow this irritation, and I have not seen any undue development of warts on hands or other parts affected, and no rodent ulcer of the face. I am not certain that the cause of the case now related is true.

A man about 48 years of age, with twenty years' service, alleged that three months before seeing me a piece of Na_2S had slipped down his waist belt and caused a sore on one side of the scrotum. At my examination he had a well-defined epitheliomatous ulcer, with deposits in the groin. He was sent to hospital, no operation was performed, and he died six months later from systemic invasion. The cause in his case was doubtful. I do not think his statement was reliable.

I have no records of malignancy in nose, throat, larynx, or lungs resulting from inhalation of $CoCl_2$, H_2S, AsH_3, or other toxic gases, and no permanent eye trouble; and I have not any indication of ulcer or growth in stomach or bowels being more common in the chemical dye industry than in other occupations.

Up to 1900 various preparations were produced in the manufacture of which arsenic acid was used. Considerable quantities of α-naphthylamine were also produced, and normally in this no arsenic would be used. The number of workmen then employed varied from 100 to 200, and there were periods when the works shut down. No records of men are available, but W. F. Dearden in 1902 had some experience with acute aniline poisoning occurring in other workmen on fast aniline black, and this was reported in the *British Medical Journal*. Up to 1910 I had personal knowledge of three men working on α-naphthylamine who died from urinary trouble due to neoplasm, and I know the names of more, but having no personal proof they cannot be included. It is possible these men might have suffered from arsenical poisoning, as we know that surgical diagnosis and treatment was then less precise.

Since 1918 α-naphthylamine has been in fairly continuous production save for a period of some months. All the men engaged on those parts of processes where there is risk in handling the material wear gloves; they are not in the open air. Others, working on distillation, are in the open air, and ordinarily do not handle the product, because pipe lines are used to transfer from one vessel to another by pressure. All the men are provided with baths, which they certainly use daily. There are good facilities for washing hands before meals, and separate lockers for working clothes and day clothes; they do not go home in working clothes; there is a canteen away from the plant for food, etc., and milk is given to each man daily.

Moreover, α-naphthylamine does not cause acute cyanosis, or any irritation of skin, nose, fauces, larynx, eyes, or stomach. For a period of six months a weekly examination by a competent analyst of carefully obtained specimens of urine yielded no indications of abnormal contents. Whereas, on another plant—distillation of nitrotoluol—workers were found passing nitro-bodies, and yet feeling quite well. This observation could not be followed up for a prolonged period for various reasons. After many years' service on plants men report a frequent desire to micturate, with possibly strangury and blood. Competent examination at hospital perhaps reveals a neoplasm at the ureteric orifice in the bladder. Some of these men have been treated by diathermy endovesically, others by incision, and have returned to work, their job being changed where possible.

I will report now the cases known amongst workers on the α-naphthylamine plant, and it is curious that cases only seem to occur amongst workmen, for staff chemists on the plant with service equally as long, and always in the odours and dust, have not so far been affected. Moreover, large amounts of this crude stuff have been used for experiments on mice by cancer research authorities, and, taking the whole length of life in a mouse in comparison with man, no pathological results were found. This stuff, when new, has a faint aromatic odour, like naphthalene. As it becomes older, or if in contact with human clothes, skin, etc., it develops an intense faecal odour similar to skatol.

URINARY DISEASES IN WORKERS CONNECTED WITH α-NAPHTHYLAMINE AND DYES PRODUCED WITH ARSENIC AS AN AGENT.

From 1880 to 1910.

During this period there were eight men who were said to have had pronounced urinary trouble. All are dead, but their history was not known to me personally. Three others, who were engaged chiefly on α-naphthylamine, are also dead—one after about fifteen years' service, one after twenty years' service, the other for an unknown period. These men were known to me and were at times treated by me. The average number of men on the job before 1910 is not known—probably 150 to 200.

From 1918.—Production of α-Naphthylamine.

R. H., aged about 56; nearly thirty years' service. Primary operation 1906; again operated on in 1911. Worked on stills, and sodium naphthionate. Died December, 1924—inoperable carcinoma of the bladder.

T. B., aged 58. Employed as farm labourer in Shropshire to 1894; in tar works to 1900. Distillation of naphthol for eight years; then charge-hand on distillation of α-naphthylamine for twenty years. Neoplasm of bladder; operation in 1927. Died in December, 1928, with extensive carcinoma of the bladder.

F. G., aged 54. In 1914 was engaged in production of α-naphthylamine. In 1915 had papilloma removed at the Royal Infirmary, and since then has been employed on other processes and work as a foreman. In 1929 he had urinary difficulty; is now under Mr. Macalpine. Not yet diagnosed as growth.

J. W., aged 56. Thirty years' service on plant (reductions chiefly). Had urinary trouble about 1917. Papilloma removed at the Royal Infirmary by Mr. Burgess. In October, 1928, had recurrence of blood in urine, pain, etc. Seen at Ancoats Hospital. Had papilloma which was treated by endovesical diathermy. Is now under Mr. Macalpine at Salford Royal Hospital. He has extensive old phthisis pulmonalis with cavitation, and is not working.

Urinary Cases in Other Departments.

1924. M. J., aged 54. Twenty-five years in works. Had urinary trouble, and was sent to Ancoats Hospital and later to the Radium Institute. He died, and at necropsy was found to have had a malignant growth of the prostate.

1926–27. K., aged 56. Twenty years' service: metaphenylenediamine, di-nitro-toluol, benzidine. Had neoplasm of the bladder, and died in 1927. H. was employed at the same place, and same service. *He also had neoplasm of the bladder and calculus.* He died in 1926. W. had the same twenty years' service as K. Was in hospital for five weeks in 1919 with acute benzidine toxaemia. Died in 1927 with growth of the bladder.

1927. W. T. was engaged for nearly thirty years in the same service as the last three cases. He complained of pain, and blood was present in the urine. He was admitted to Crumpsall Infirmary, and died. *Post-mortem examination disclosed lymphosarcoma* of the abdomen invading the bladder. N., aged 56, had nearly thirty years' service; *at first for some years in the warehouse at the works.* He was for ten years on the sulphuric acid plant; later on metaphenylenediamine. For the last ten years he was weighing barrels of finished dyes. At necropsy he was found to have extensive growth of the bladder.

1924. W. and D., *young men of 25 to 30 years of age, of short* service; employed in grinding diphenylguanidine. They had serious urinary pain, but no haemorrhages. They left the works, and their further history is not known.

1924. R. J., aged 42, was employed in the works for five years. He died in Crescent Road Hospital with malignant growth of the bladder S. was employed for many years in drying finished dyes in stoves, *mainly of triphenylmethane type. He had dysuria and* blood in urine in 1925. *Was operated on for papilloma at the* Royal Infirmary. He is still living, but not at work.

1926–27. W., a big, 16 st. *man of 30.* Was employed on naphthalene intermediates—sulphonations, nitrations, and reductions. Had pain, and blood was present in the urine. He was seen and treated by Mr. Macalpine. *No neoplasm was found.* He is now working as a mechanic, and is well.

1927. A. had dysuria and blood in urine. He was working on cyanide crushing; no connexion established. He is quite well.

1928. T., aged 60, has had fifteen years' service on azo colours. He had blood in the urine and was treated by his own doctor. He is well and still at work.

The urines of several of the above employees were analysed, but yielded no evidence of toxic bodies.

Non-urinary Cases.

1930. Incog.; employed on various products; had carcinoma of the caecum.

1924. R. H. *was employed on various products—intermediates* and triphenylmethane; also, prior to this engagement, for many years on phenol distillation. He had carcinoma of the pylorus and died.

1927. K. C. suffered from epithelioma of the scrotum, said to be due to Na_2S; deposits in abdomen. He died.

Owing to the fact that many of the men previously had worked on processes other than α-naphthylamine, and some never on α-naphthylamine at any time, it is, in my opinion, impossible to assume this to be the most potent agent. If it were possible to have men under medical observation for a long period of years in works solely concerned with the making of α-naphthylamine, and not near any contaminating plant, and a staff of men with no previous chemical history, we might be able to trace the irritant. So far we cannot arrive at any true percentage of cases in general, owing to the following facts: (*a*) men sometimes employed on one job, then on another; (*b*) *irregular operation of the plant owing* to trade; (*c*) no proper history of men after leaving the works.

THE EFFECT OF RADIATION ON THE RESISTANCE OF RABBITS TO INFECTION WITH VIRULENT STAPHYLOCOCCI.

BY

ALBERT EIDINOW, M.B., B.S.LOND.

(From the National Institute for Medical Research, Mount Vernon, Hampstead, N.W.3.)

INTRODUCTION.

THE *clinical study of disease treated by general light baths* suggests that the absorption of rays of light by the skin increases the general resistance of the body to bacterial infection. The curative action of light has been successful not only in surgical tuberculosis, but in certain bacterial diseases of the eye, mucous membrane, and skin. Recent research *on the action of light in the cure and prevention* of rickets has proved that this disease is due to deficiency of vitamin D, and that irradiation causes the production of vitamin D from ergosterol in the skin and the absorption of this vitamin. Up to the present the experimental work on the effect *of irradiation on resistance to infection has* been *limited and contradictory. Rhode*[1] *found that irradiated guinea-pigs* were *less susceptible to inoculation* of saline emulsion of tuberculous sputum than control animals. These experiments were repeated by Hase,[2] but his results were negative. Mayer[3] carried out a similar series of experiments, and infected guinea-pigs by inhalation; his results *indicated a possible increase in* resistance when irradiation preceded infection. C. M. Hill and Janet H. Clarke[4] tested the effect of ultra-violet radiation on the resistance of rats to a culture of pneumococci; their conclusions signify some possible benefit if irradiation precedes infection. In their experiments shaved rats were exposed to a *quartz mercury vapour lamp; the skin of* some of the animals was severely burned, and this suggests that the results of their *experiments may be associated with* the effects of local necrosis or inflammation. Animal experiments of this nature are difficult, for it is impossible to study the effects of repeated applications of short ultra-violet rays *on small areas of skin unless the hair is shaved* or removed by a depilatory. This would mean that such *animals would have* to be almost completely shaved if the principles of "short-ray therapy" were correctly adopted.

The "minimal erythema dose" of ultra-violet rays applied to an area of skin-equivalent to 20 to 30 sq. cm. per kilogram of weight increases the bactericidal power of samples of defibrinated blood, collected one to two and a half hours following irradiation, and tested *in vitro* by the "slide cell technique" of Wright, Colebrook, and Storer.[4] Colebrook suggests that this effect is due to *increased function of the leucocytes. My own experiments*[5] on living animals suggest that following irradiation of the surface layers of the skin a photo-biochemical reaction occurs, and a bactericidal substance is first produced locally at the site of irradiation and is carried by the blood stream into the general circulation. So far experiments have *failed to demonstrate bactericidal activity in extracts* of irradiated skin or other tissue cell emulsions—that is, liver, spleen, testes, brain, and thymus. When defibrinated blood is directly irradiated, the bactericidal properties are diminished and the leucocytes are damaged. The intravenous injection into the living animal of irradiated blood cells *and other tissue cells (testes, liver, thymus) is followed* by an increase in the bactericidal power of the blood as tested *in vitro*.

The correlation of the bactericidal power of the blood so tested with the resistance to infection is so far indefinite. *While some of the tests on human blood show a high bactericidal effect during acute pyrexial infections*, a low *haemo-bactericidal power and an impaired efficiency of the* leucocytes must be regarded as giving an unfavourable prognosis. The effects of irradiation and of many chemotherapeutic substances are only of a transient nature; it has not been possible to discover an innocuous therapeutic agent which can produce a high haemo-bactericidal action for a prolonged period. The majority of the bactericidal compounds rapidly disappear from the blood stream and are quickly excreted; others are less soluble, are retained within the tissues, and are slowly eliminated. *There is no suitable* "*in vitro* technique" to estimate the resistance of the *fixed cell or tissue immunity, and this increases the diffi*culties of assessment of resistance by experimental methods.

P. Hartley[6] has shown that the exposure of immunized animals to ultra-violet rays is without effect on the content of diphtheria antitoxin or typhoid agglutinins of their serums. The conclusion which can be drawn is that the *biologically active ultra-violet rays shorter than 3,100 A.U.* appear to have some power to increase the "non-specific" immunity of the blood cells, but not the specific immunity. M. Hardy[7] has summarized the effects of measured amounts of ultra-violet rays on the blood cell count of animals. The conclusions from her observations agree with those of Trangott,[8] Aschenheim and Meyer,[9] Cramer,[10]

Laurens and Sooy,[11] Gunn,[12] and Sooy and Morse,[13] who all showed that irradiation of the skin increased the numbers of blood platelets, especially if they were abnormally low. Successive small doses of light had no effect on the total white count, but intensive irradiation between 3,000 and 2,750 A.U. increased the number of polymorphonuclear cells. Other observers have reported a leucocytosis and a relative increase of lymphocytes.

In conclusion, the observations obtained by experimental methods which support the theory that irradiation can increase the body resistance against infection are summarized below:

1. Antibody production may be increased by heat effects due to the absorption of infra-red and luminous rays.
2. The haemo-bactericidal power is increased by the action of ultra-violet rays from 3,100 A.U. on the skin.
3. Bactericidal substances may be formed by photo-biochemical reactions.
4. The erythema reaction causes changes in the capillary circulation and causes an intradermal polymorphonuclear leucocytosis.
5. Prolonged radiation causes an increase in total number of blood platelets and white cells, and a possible relative lymphocytosis.
6. Radiation *may* influence the function of the endocrine system, as shown by the effect on the suprarenal and thyroid glands.

SCHEME OF EXPERIMENTS.

During the past four years the bactericidal power of the blood has been tested *in vitro* against a stock culture of staphylococci. It has been found that one to two hours after the application of an erythema dose of rays shorter than 3,100 A.U. the haemo-bactericidal power tested *in vitro* was temporarily increased. These results have been accepted by some as evidence suggesting that irradiation of the skin increases the resistance against infection. Conversely the significance of these results has been disputed by others, who maintain that effects of irradiation are due only to erythema and counter-irritation of the skin, and the test of the haemo-bactericidal power is no index for increased resistance or immunity.

I have therefore planned a series of experiments to study the effects of irradiation on the resistance of living animals to infection. To avoid the controversy of the erythema reaction produced by short ultra-violet rays, a source of light was used by which the short ultra-violet rays were omitted and radiation to infra-red, luminous, and ultra-violet rays up to 2,850 A.U. could be applied for a prolonged period without the production of skin reactions. This method is similar to solar irradiation. Animals were infected by an intravenous injection of the same stock broth culture of staphylococci as was used in the haemo-bactericidal tests. An intravenous injection of 0.6 c.cm. of this culture was found to be constantly lethal to normal rabbits weighing about 2 kilograms.

Three groups of experiments were performed, and in each series of experiments a suitable number of normal rabbits were infected and kept in the dark, so that control observations could be made as to the virulence of infection. The series of experiments described are:

GROUP A: The effects of radiation before infection.
GROUP B: The effects of radiation directly after infection.
GROUP C: The effects of radiation before and directly after infection.

Method.

Young rabbits each weighing 1,500 to 2,200 grams were selected. Each experiment was carried out with groups of four or six treated animals, and two control untreated animals. In some cases the hair of the back was removed by means of a depilatory (calcium sulphide) one or two days previous to irradiation. These animals were carefully weighed before infection. All animals were fed on a daily diet of oats and water, and a green vegetable once or twice a week.

Technique of Irradiation.

Each rabbit was kept in a wide-meshed wire cage. Irradiation was carried out in a special treatment cubicle. The source of light employed was my new daylight lamp, which has already been fully described.[14] The spectrophotographic examination showed that infra-red, visible, and ultra-violet rays up to 2,850 A.U. were transmitted. The relative intensity of visible and long ultra-violet rays was high, and in this respect the source of light was more comparable with solar radiation than other artificial sources of light. With the normal white skin it was possible to produce erythema, but only after many hours' exposure. At a distance of 30 inches a standard culture of infusoria was killed in 120 minutes; a surface culture of staphylococci was killed in 150 minutes. The acetone methylene-blue gauge was bleached from 9 to 7.5 units after twenty-four hours' exposure. The lamp was placed in a horizontal position. All animals were exposed at a distance of 4 feet. A small motor fan was kept running in the cubicle to control the possibility of overheating; the temperature was kept at 20 to 22° C. The rectal temperatures of the animals were observed during irradiation. With this source of light prolonged exposures of forty-eight hours could be applied without the dangers of the production of severe erythema, oedema, or necrosis of the skin. In a general way this was similar to solar radiation.

Cultures and Technique of Infection.

The culture of staphylococcus employed in these experiments was a stock culture which had been periodically "passaged" through rabbits and was found to retain its virulence. Subcultures were made from the stock culture by adding 50 c.mm. to 5 c.cm. of Hartley's broth; fourteen to sixteen hour cultures were always used. Rabbits were infected by 0.6 c.cm. of a broth subculture injected intravenously into the lateral vein of the left ear.

RESULTS OF EXPERIMENTS.

Control Animals.

Total number of normal rabbits infected intravenously with 0.6 c.cm. of broth culture of staphylococci	22
Total number which died	22
Average length of time alive	under 24 hrs.
Average weight (grams) of control animals	2,054

Grouping together the control experiments, 22 normal rabbits were given an intravenous injection of 0.6 c.cm. of broth culture of staphylococci. All these animals died within twenty-four hours. Before death the rabbits were in a state of coma, breathing rapidly, and showed a rectal temperature of 106–107° F.

Post-mortem examination invariably showed acute pericarditis with 1 to 2 c.cm. of serous or sero-purulent fluid in the pericardial cavity. Heart blood cultures were positive, and grew abundant colonies of staphylococci. Occasionally a haemorrhagic congestion or oedema of the lungs was seen. Death was due to acute septicaemia.

GROUP A.—*Irradiated before Infection.*

Total number of rabbits irradiated and later infected intravenously with 0.6 c.cm. of broth culture of staphylococci	30
Total number which ultimately died	26
Total number alive	4
Average number of days alive (lethal time)—from 26 animals	7.43
Average weight (grams)	1,844.3

All these animals lived longer than the controls, which were not irradiated. Of 22 animals which were irradiated for 48 hours:

The number which lived for only 24 to 48 hours	6
The number which lived for 3 to 7 days	5
The number which lived for 8 to 14 days	5
The number which lived longer than 14 days	6

Two of the latter have lived over 60 days, and the remaining four are still alive.

Eight rabbits were exposed for short periods—that is, two to twelve hours. Two of these animals were only exposed for two hours, and died within twenty-four hours. Of the remaining six rabbits:

Number which lived for 24 to 48 hours	2
Number which lived for 3 to 7 days	2
Number which lived for 8 to 14 days	1
Number which lived longer than 14 days	1

Post-mortem Examination.—The irradiated animals which died within twenty-four to forty-eight hours showed pericarditis with serous effusion, broncho-pneumonia, a positive blood culture, and death from septicaemia; some of these animals had petechial haemorrhages of the bowel. Rabbits which died after three to fourteen days had a dilated heart and myocarditis; multiple pyaemic abscesses were present in the myocardium varying in size from less than a millimetre in

diameter to 4 mm. Serous effusion, empyema, and purulent effusions were seen in the pleural cavity, with collapse of the lung, abscess formation, or purulent broncho-pneumonia. Multiple abscesses of both kidneys were frequent. Death was due to pyaemia, and the heart blood cultures were mostly positive. Rabbits which died after fourteen days showed myocardial failure; the heart was very dilated, and showed degeneration of the muscle due to myocarditis; fluid was present in the pleural and peritoneal cavities; the liver and kidneys showed changes typical of a failing circulation. The heart blood cultures of these cases were negative.

Estimation of Haemo-bactericidal Power.—Samples of defibrinated blood were collected before, during, and at the end of irradiation, and the bactericidal power against the broth cultures of staphylococci was determined. The average results from these tests indicate that the haemo-bactericidal power became slightly higher during irradiation than it was in the same animals before they were irradiated, and also higher than in control animals. This increase in haemo-bactericidal power is not as great as the results which have been obtained by irradiation with the short erythema-producing ultra-violet rays. It may be noted that the results of the tests of haemo-bactericidal power expressed in terms of the percentage average of colonies of microbes which were killed was only increased 8.5 per cent. at the end of forty-eight hours' irradiation. This was the period when many of the irradiated animals were infected.

Estimation of the Total Number of Corpuscles.—Blood counts were carried out in normal and irradiated animals. The total number of red blood corpuscles per cubic millimetre was not greatly changed, but prolonged irradiation increased the total number of leucocytes. Differential blood counts showed no change, and the relative lymphocytosis could not be confirmed.

Rectal Temperatures.—Prolonged radiation by the technique which has been described did not alter the rectal temperatures of rabbits to any marked degree.

GROUP B.—*Irradiation Directly After Infection.*

Total number of rabbits irradiated directly after intravenous infection with 0.6 c.cm. of broth culture of staphylococci	11
Total number of animals which died	10
Number still alive (56 days)	1
Average number of days alive after infection ...	2.9
Number of animals which lived 24 to 48 hours after infection	9
Number of animals which lived longer than 14 days after infection	2
Average weight (grams) of rabbits used in Group B experiments	2,127.2

These animals were injected with 0.6 c.cm. of a fifteen-hour broth culture of staphylococci, and were irradiated immediately after, irradiation being continued till death or for forty-eight hours. The shaved animals responded better than unshaved rabbits. Except for two animals which survived for seventeen and over fifty-six days, the irradiation had no marked effect, for the remainder died within forty-eight hours. Post-mortem examination showed acute pericarditis with serous effusion and haemorrhagic oedema of the lungs; heart blood cultures were positive. In all the experiments the rabbits were very ill during the first twenty-four hours following inoculation, and the rectal temperature was 105° F. to 107° F. During this acute pyrexial stage exposure to light was harmful; this view is supported by similar experiments on infected albino rabbits, all of which died rapidly when exposed to light.

GROUP C.—*Irradiation Before and Directly After Infection.*

Total number of rabbits irradiated before and directly after intravenous infection with 0.6 c.cm. of broth culture of staphylococci ...	12
Total number which died	11
Total number alive	1
Average number of days alive after infection ...	2.1
Number of animals which only lived 24 to 48 hours	10
Number of animals which lived longer than 14 days	2
Average weight (grams) of rabbits used in Group C experiments	1,612.5

These animals were exposed to the daylight lamp for forty-eight hours. They were then each given an intravenous injection of 0.6 c.cm. of a fifteen-hour broth culture of staphylococci, and were irradiated immediately after, irradiation being continued till death or for forty-eight hours. Except for two shaved rabbits which lived for thirteen days and over thirty-five days (still alive), these animals did not show any marked increase of resistance compared with controls kept in the dark or the Group B experiments. Irradiation during the acute pyrexial stage of illness not only failed to have any beneficial action, but antagonized the good effect of previous irradiation.

COMMENT.

It is difficult to assess the effects of radiation by clinical methods, for the variation of factors cannot establish the absolute figures necessary for statistical data. The general impression which has been recorded supports the view that irradiation increases the resistance against infection and improves the general health. In many cases this impression has been entirely based upon subjective data. Maughan and Smiley,[15] working with students at the Cornell University, have shown that the frequency of colds in "cold susceptible" students was reduced 40.3 per cent. by weekly exposure to moderate irradiation from a mercury vapour lamp. In the experiments which have been described prolonged irradiation of rabbits increased their resistance, insomuch as a rapid infection by an acute and virulent staphylococcus was checked, and a subacute or chronic pyaemic infection slowly progressed. The irradiated animals showed a lethal time average of 7.43 days. Although the average weight of the control rabbits was higher than the average weight of the irradiated animals (Group A), these animals all died within twenty-four hours. There was no marked erythema or skin reaction following prolonged irradiation, so that the results in this series cannot be attributed to counter-irritation or local inflammation. The observations from experiments carried out *in vitro* indicate that an increased haemo-bactericidal power and an increased leucocytosis occur during irradiation. The bactericidal effect was not as big as the results which have been previously obtained one to two hours after irradiation of the rabbit's skin with an erythema dose of rays from a quartz mercury vapour lamp. At present it is impossible definitely to associate the results of haemo-bactericidal tests *in vitro* with resistance to infection *in vivo*. These experiments prove that the intensity of infection was arrested, for although the rabbits in Group A were unwell for twenty-four hours after infection, some made a progressive recovery, while the remainder steadily lost weight and died after three to eleven days of pyaemia. During the stage of infection, irradiation was not sufficient to withstand the rapid and acute bacterial invasion. It is possible that the absorption of infra-red and luminous rays increased the pyrexial state and accelerated death, for the onset of exhaustion, dyspnoea, and coma was more rapid with unshaved infected rabbits. It would be of interest in the future to repeat these experiments with a slowly progressive infection and also to observe the results by short ultra-violet radiation.

Green and Mellanby[16] have suggested that animals deficient of vitamin A are more susceptible to pyaemic infection, and their recent experiments on the treatment of puerperal septicaemia by radiostoleum support their theory. It is known that vitamin D can be produced by irradiation of the skin, and it has been suggested that the activation of this vitamin by irradiation may influence resistance to infection. As a control experiment I have recently given six rabbits a daily dose of 1.0 c.cm. of radiostoleum (which contains both vitamin A and D) by mouth for twelve successive days; after this period the animals and two control untreated rabbits of similar weight were given an intravenous injection of 0.6 c.cm. of the same broth culture of staphylococcus as was used in the experiments on irradiation. All eight animals have died within twenty-four hours from acute septicaemia. This indicates that the nature of the protection given by irradiation in these experiments was not due to either of these vitamins.

SUMMARY.

1. Previous prolonged irradiation of rabbits with a "daylight lamp" emitting infra-red, luminous, and ultra-violet rays up to 2,850 A.U. increases their resistance against virulent infection with staphylococci.

2. Experiments *in vitro* show that after forty-eight hours' irradiation the haemo-bactericidal power is increased and a general leucocytosis is produced. There is not, however, sufficient evidence to correlate these results with the increased resistance to infection. In the case of the haemo-bactericidal power as measured *in vitro*, the evidence obtained indicates that a high bactericidal power of the blood was not maintained during this method of prolonged irradiation.

3. Irradiation of rabbits with an identical technique, after infection with virulent staphylococcus, gives no protection.

4. Experiments indicate that the results are not due to the production of vitamins (A or D).

This research was carried out in Professor Leonard Hill's laboratory at the National Institute for Medical Research, Hampstead. I am greatly indebted for his kindness, constant advice, and help during the progress of these experiments.

THE RELATION OF EAR CONDITIONS TO BATHING.

BY

W. I. DAGGETT, M.A., M.B., F.R.C.S., JUNIOR NOSE AND EAR SURGEON, AND R. COVE-SMITH, M.A., M.B., M.R.C.P., MEDICAL REGISTRAR, KING'S COLLEGE HOSPITAL.

As the bathing season is now at its height, it does not seem out of place to set down some of the dangers which are liable to beset the community at this time of year. The daily papers are taking an increasing interest in the health of the populace, yet insufficient attention has been drawn to the precautions necessary for those who wish to avoid the inconveniences which may result from careless indulgence in swimming. Many medical men allow their patients too much licence in this direction, and fail to pay attention to small details which would increase the comfort of all.

It is obvious to those who attend out-patients in any large ear, nose, and throat clinic that a great number of acute aural conditions develop as the result of bathing. Moreover, such conditions may have dangerous sequels. For a long time at King's College Hospital we have had a notice placed in the out-patients' department which warns patients against bathing without leave from the surgeon.

From the point of view of the ear, nose, and throat surgeon the bathing community can be divided into (1) healthy persons; (2) those with septic nasal conditions (including the common cold); (3) those with a perforation of the tympanic membrane; (4) those with recurrent dermatitis or furunculosis of the external auditory meatus.

As regards persons in normal health, the public has a vague idea that water introduced into the meatus may be dangerous, and cotton-wool and other substances are used to prevent this. In such persons the entry of water does no harm, though it may give rise to several unpleasant symptoms. Among these are deafness and tinnitus following immersion. This is due to the swelling of wax and occlusion of the meatus, or to water collecting behind an accumulation of wax, where it may remain for some time. Another cause is the foolish practice of drying the ears with the rolled-up corner of a towel, thus pressing down against the drum any wax that may be in the meatus. Some may complain of a transitory earache due to cold water impinging on the drum, but this symptom should not be "passed off" without thorough examination lest acute otitis media be the cause. We have not yet met a case of vertigo; in fact, this is hardly to be expected, as cold water enters each meatus with equal caloric stimulus to both labyrinths, so that the labyrinthine equilibrium remains undisturbed. The possibility of the occurrence of such a symptom must, however, not be overlooked, for it could occur if one meatus was occluded and the other patent.

Too often acute otitis media, with or without dangerous complications, occurs in the healthy swimmer. This is due to the entrance of infected water into the Eustachian tube and middle-ear tract. Public swimming baths and "town" rivers are great sources of danger. Those who bathe in the sea or in mountain streams are usually exempt from trouble. The healthy Englishman is fond of swimming, and in the large towns public baths afford the only facility. There is therefore a crying need for those in authority to render the public baths as safe as possible. It is essential that constant inspections should be undertaken. The problem is a difficult one, for disinfectants cannot be introduced in sufficient concentration without rendering bathing irksome. Calcium chloride is used in many places; it imparts a somewhat unpleasant taste to the water, and usually gives rise to a mild conjunctivitis. Naturally water is not rendered safe by this means, but if continuous filtration is carried out as well the risk is minimized. It is interesting to note that we have not been able to trace more than an isolated case of ear trouble attributable to bathing in the Camberwell baths, where this method is practised. In far too great a proportion of public baths the water is not changed often enough, whilst scouring of the empty bath is inefficiently carried out. It should be made compulsory for bathers to wash with soap before entering; in Germany this is an almost universal practice. Again, it is a bad principle that bathers should be allowed to come in straight from the streets and tramp along the sides of the bath in their grimed boots. All this filth must sooner or later find its way into the water.

The present facilities for bathing will not be revolutionized for some time, so we must consider what type of swimmer tends to develop acute otitis media and how the risk may be minimized. As a rule it is the badly taught, inexperienced swimmer who suffers most and becomes the victim of an "acute ear." Correct breathing is essential to prevent the entry of infected water into the Eustachian tubes, and it is here that the tyro fails. The practised swimmer fills his lungs at regular intervals through the widely opened mouth, keeping the soft palate raised and thus shutting off the nasopharynx. In fact, many swimmers of repute continually have the mouth open, even under water, gradually blowing air out until they need a fresh inspiration, when the head is turned clear of the water and air taken in through the mouth. The inexperienced swimmer fails to regulate his breathing properly, draws the water into his nose, chokes, and swallows; this last action opens up the Eustachian tubes and water is allowed to enter. For the same reason it is unwise to "duck" suddenly or to push a friend in unawares; proper inspiration is difficult in such crises. Jumping in from a high board should not be practised without holding the nose, as the sudden inrush of water into the nostrils may force some into the sinuses or into the Eustachian tubes.

It will be argued that thousands of people in normal health bathe regularly without precautions and come to no harm; nevertheless, the risk is there, and correct breathing should be taught.

The second class, those suffering from septic nasal conditions (including the common cold), should not be allowed in public baths. Not only do they spread infection, but any water entering the nose may carry infection backwards into the nasal accessory sinuses or Eustachian tubes. Swimming is dangerous in the same way as the pernicious habit of sniffing salt and water up the nose to relieve the common cold.

Patients who have a perforated tympanic membrane often ask whether bathing is permissible. Whether or not there is discharge the answer should be an emphatic "No." Those in whom the discharge has ceased will almost certainly become reinfected, with consequent exacerbation of old trouble; whereas those with an active discharge will contaminate the water and lay themselves

open to the risk of added virulent infection and acute symptoms supervening on the chronic. The professional or expert swimmer may possibly be excepted if the ear has been dry for two years or more, although the perforation has not healed, but every precaution must be taken as regards breathing and against the entry of water into the meatus. No form of precaution is "foolproof," though a small piece of wool impregnated with vaseline and laid in the meatus may serve a useful purpose. Better still, a thin piece of wool may be laid over this and kept in place with collodion. A successful radical operation, one year after complete healing, places the patient in Class 1 (healthy persons) as regards bathing. Patients with acute or chronic meatal eczema or recurrent attacks of meatal furunculosis are best advised not to bathe, for exacerbations are only too common.

Many swimmers who make a practice of diving into deep water complain that when they go beyond a certain depth they get a violent singing in the ears. This is as a rule temporary; it is partially due to prolonged holding of the breath and partially to increased pressure on the tympanic membrane and stapes. Should it persist it will probably be found that there is some degree of Eustachian obstruction and retraction of the tympanic membrane and that politzerization will relieve the noises.

Conclusions.

1. There should be regular and frequent inspections of all public baths, and the water should be maintained as pure as possible.

2. All swimmers should be compelled to wash with soap under a shower before entering a public bath.

3. The public should be educated as regards correct breathing in the water.

4. "Ducking" and pushing people in should be discouraged.

5. Those persons with colds, septic nasal conditions, perforated ear drums, or recurrent inflammatory conditions of the external auditory meatus should not be allowed in public baths without leave from an aural surgeon.

ARSENICAL POISONING:

WITH SPECIAL REFERENCE TO TREATMENT WITH THE GALVANIC CURRENT.

BY

C. H. C. DALTON, M.A., M.D., D.M.R.E.,

MEDICAL OFFICER IN CHARGE OF X-RAY AND THERAPEUTIC DEPARTMENT, EAST SUFFOLK AND IPSWICH HOSPITAL.

THE following case is of exceptional interest both scientifically and also from the practical aspect. It suggests strongly that the continuous galvanic current should be used in cases of arsenical poisoning, and also in other cases in which it is found that the toxic factor carries a positive or negative charge.

Mr. X, aged 40, had been an arsenical worker from 1919 until September, 1928; during this period he had a number of attacks of "indigestion" and colic following exposures to arsenic, and also various sensory changes from time to time. On April 6th, 1929, a sudden "foot-drop" occurred, and he attended for treatment on April 10th.

On physical examination, voluntary movement involving the anterior tibial and peroneal groups of muscles was absent; the skin over the middle third of the right leg in front showed diminished sensation. The muscles were tested, and the electrical reactions showed a normal response to the faradic current with the exception of the extensor longus digitorum, which, however, reacted briskly to the galvanic current.

Treatment was carried out three times a week, the affected muscles being stimulated by interrupted galvanism. In addition, the continuous galvanic current was applied by means of foot-baths, and a pad was placed reaching up the shin of the right leg; the negative pole was attached to the bath, which contained the right foot. The idea of this was that arsenic would be likely to be present in the form of the hydrochloride, and that the alkaloid would be extracted by this means.

After about a fortnight it was noticed that the skin on the right leg was becoming markedly scaly, and as this was most unusual I suggested that arsenic was being extracted. In consequence of this I collected some of the fluid from the pad at the end of one treatment, and also a sample of scales which were brushed off the skin of the leg. Both these samples were tested by an expert analytical chemist, and arsenic was reported to be definitely present by Marsh's reaction.

After three weeks' treatment, voluntary movement of the peronei began to return, and was followed a fortnight later by the tibialis anticus. Treatment was terminated on May 30th, when the condition had almost approached the normal; the extensor longus digitorum would contract to galvanic stimuli, but not to the faradic current. A further test, on June 6th, revealed that all the muscles would contract to the faradic current. On June 20th the affected muscles had completely recovered, and normal sensation of the skin on the front of the right leg was found to be present.

The continuous galvanic current is known to have an attractive or repulsive action to all substances which carry a negative or positive charge. Medical electro-therapeutists are frequently criticized because they are unable to give proof of how their methods act, and it is always satisfactory when it is possible to do so without question or doubt.

Similar work to the above has been carried out, I believe, in cases of lead poisoning, and also in the treatment of gout, but I can find no case on record in which arsenic has definitely been proved to be present chemically following treatment by the galvanic current. There can be no doubt that a considerable quantity of arsenic was extracted in the course of treatment, and the rapid recovery of the patient suggests, further, that this is the correct procedure in these cases.

The Sections.

SUMMARY OF PROCEEDINGS.

(*Concluded from page 263.*)

SECTION OF MEDICINE.

Friday, July 26th.

ASTHMA.

DR. F. PARKES WEBER occupied the chair on the third morning of this Section, and called upon DR. ARTHUR F. HURST to open a discussion on asthma. Dr. Hurst began by remarking that the oft-repeated hopes of a panacea were still far from realization. He drew attention to the importance of studying the constitution or diatheses of sufferers from asthma. There must be a lack of balance, due to some chemical cause, between the vagus and the sympathetic system, in asthmatic persons, resulting in a preponderant activity of that part of the vagal nuclei that regulated the contraction of the bronchial unstriped muscle. He further discussed the subject of abnormal sensitiveness to proteins and other chemical substances; the nasal and other conditions that might give rise to reflex asthma; and the psychological factors that might bring on asthma in any asthmatic subject. As for treatment, the only cure should be a change in the constitution or in the chemistry of the blood of the asthmatic person: the diet must always be a matter of great importance, and so must altitude. The skin tests he described as valueless in asthma, though in hay fever they were often valuable. Nasal treatment he thought was often most useful in selected cases. Asthma powders he condemned, but the use of adrenaline was commended on physiological grounds. In status asthmaticus the continuous injection of adrenaline in small quantities (up to even a drachm in half an hour) was the only cure. DR. JAMES ADAM (Glasgow) said that for thirty years he had held that there was a toxic basis in asthma and that in most cases the nasal condition was a most important factor. This toxaemia, which originated in the intestine and the tissues, was partly due to the absorption of nitrogenous poisons and partly to an error in nitrogenous metabolism, the result of imperfect oxidation or enzyme action. The toxaemia tended to show itself first as a catarrh and

later as a spasm in the respiratory tract. This conclusion was based on eight observations: (1) the frequent recurrence of asthma in working folk at week-ends, when overfeeding and under-exercise predominated; (2) evidence was usually obtainable in asthmatics of neglect of the alimentary and skin functions; (3) asthma patients lost their complaint temporarily during the activities of the war years; (4) periodicity was a common feature of the case records; (5) the common complications of eczema and urticaria responded promptly to dietetic treatment; (6) the start of asthma was before the 15th year in 50 per cent. of all cases; (7) in this time of life infections were common; and (8) detoxication was a potent remedy. Moreover, the urea content in the blood and urine of asthmatics was reduced, and ammonia was increased in the urine. Dr. Adam then submitted further biochemical and clinical evidence in support of asthma being a toxicosis. He believed that its incidence was increasing owing to the greater complexity of modern civilization, more marked tendency to indoor life, perverse use of body organs, and defective foods. Allergy, though an interesting feature in about 50 per cent. of asthmatics, was not the most important factor; a so-called history of heredity was no bar to cure. Special treatment of the nose was necessary and mouth breathing must be stopped. Professor R. J. S. McDOWALL, from the physiological standpoint, enumerated the various ways in which different stimuli, such as local irritants, injections of peptone and histamine, nervous excitation, and psychic factors, might bring about an asthmatic attack. He then discussed in detail the part which might be played by the vagus, and mentioned that he had recently shown that peptone injections greatly increased the sensitivity of this nerve. This appeared to be a key of some importance in the asthma problem, but the abnormal proteins probably caused also a temporary bronchial constriction which was seen in an enhanced form in typical anaphylaxis. This increased sensitivity was not limited to the bronchi and heart, but extended to the autonomic nervous system, including the visceral vessels. The speaker then passed to consider how such abnormal proteins might enter the body, and the part played by the amino-acids, certain of which in the protein molecule might have a special significance. Thus, he remarked, the many divergent views about asthma might be fitted into a simple picture; it would be possible also to harmonize the different kinds of treatment for which success had been claimed. Each case had to be dealt with according to its nature, but a combination of treatments was sometimes desirable. When the nature of sensitization was discovered the cause of asthma would be revealed and also the etiology of a large number of allied diseases. Dr. G. H. ORIEL gave an account of the physiological chemistry of asthma, and of the deductions as to its causation that might be made from the various examinations of the tissues and secretions. He outlined the possibility of a urinary test for asthma which was now under investigation; a specific substance was apparently present in the urine of asthmatics. He spoke of the use of glucose in the treatment of asthma in children. He defined asthma as a symptom rather than a disease. Dr. E. WATSON-WILLIAMS (Clifton) emphasized the importance of toxaemia, and stated that in his opinion the cases of asthma due to a nasal reflex were not many. He discussed the effects of bronchial contraction and expansion in the asthmatic attack, comparing them with the process whereby the newborn infant first aerated his solid lungs. Dr. HARRINGTON agreed that asthma was toxaemic in the great majority of cases, if not in all. Treatment should be on the lines indicated by this supposition—detoxication. Stress was laid on the importance of correct diet[illegible] iber of illustrative cas[illegible] of young children with milk was deprecated. The resumption of bad or unhealthy conditions of life would cause relapse in any cured asthmatic; cure was a relative term, and its maintenance depended on the good will of the patient. Dr. WHERRY alluded to the nasal factor in asthma, pointing out the abnormal excitability of the nasal mucosa in all asthmatic patients. He believed this to be the main element in the etiology of these cases. The treatment of asthma should therefore have the nose and its adjoining structures as its chief theatre. Other contributory factors such as overwork and unsuitable diet were mentioned; loss of sleep was described as one of the worst results of the attacks; it should be treated by medinal rather than by adrenaline. Dr. CAMPS (Teddington) discussed treatment by inhalations of oxygen and adrenaline, which he had employed in cases of every type. This treatment saved much trouble, and its nightly use might break the asthma habit; it would also stop an attack of asthma. Dr. J. SPEARES (Dublin) dwelt on the difficulties induced by ignorance of the causation of asthma, an incurable constitutional disorder. In certain cases vaccine treatment had given him good results.

Dr. HUDSON's contribution to the discussion took the form of a lantern demonstration of experimental bronchial muscular movements. During inspiration the tubes widened and lipiodol injected into them was seen to outline a tube wider than it was in expiration. Evidence of the existence of an atrial sphincter was obtained. In bronchiectasis the lipiodol did not change its position in respiration. Films taken in cases of asthma showed the tubes to be small and their permeability to lipiodol much reduced; the oil failed to reach the bronchioles. The bronchi narrowed with expiration and widened in inspiration of their own motion and without the interference of any external musculature. Dr. HURST briefly replied to a number of the points raised in the course of the discussion, demonstrating his view that in asthma the bronchial spasm was expiratory and was aggravated by the fact that the expiration was forced. He added that in pure asthma true emphysema did not occur. The breathing exercises for an asthmatic child or adult should be expiratory and not inspiratory, and should include nose breathing also if necessary. The treatment of constipation he believed to be harmful in most cases, and he objected similarly to the Plombières douche treatment. Ephedrine he thought less useful than adrenaline, unless perhaps in the milder cases of asthma; in actual attacks it was of little service. Caffeine was a more useful drug in doses of 6 or 8 grains of the citrate, taken early in the day and not at night. The meeting of this Section was attended by over 180 members.

THE HALOMETER.

Dr. FRANK C. EVE (Hull) described an instrument he had devised for facilitating the diagnosis of certain blood diseases. (See *British Medical Journal*, July 13th, 1929, p. 48.) He said that this instrument, the name of which should be pronounced halo-meter, indicated the average size of red cells in a blood smear by measuring the diffraction halo they produced. Dr. Eve said that as enlargement of the red cells was the earliest sign of pernicious anaemia, this difficult diagnosis was rendered rapid and easy. In fact, the syndrome of the early stage revealed by the instrument was often so dissimilar to the syndrome usually described that a separate name, such as pre-pernicious anaemia, seemed necessary. The two syndromes could be combined into a single definable disease (megalocytic anaemia) if a ready means such as the halometer was found of measuring red cells. In cases where the enlargement of the red cells was too slight to warrant a definite diagnosis of pernicious anaemia, liver might be given for two months. If the red cells were thereby restored to normal size the diagnosis was confirmed. The halometer was the readiest means of checking (weekly) the efficacy of treatment by liver or its extracts. In "cured" cases it should be used every quarter to detect incipient relapse. Dr. Eve found it necessary to measure the red cells in all cases of glossitis, tingling of the extremities, achlorhydria, obscure anaemia or loss of energy and weight, bleeding from the bowel, and even cholecystitis. A thin blood smear was essential—produced by pushing (like a plane) a small drop of blood along a grease-free slide. Dr. Eve said he had found the halometer reliable in that he had yet to meet the case where its diagnostic verdict had been proved erroneous by time or by other clinical evidence. Similarly with subacute spinal degeneration, but less absolutely because occasionally the neurotoxic poison was at first unaccompanied by the haemolytic,

SECTION OF SURGERY.

Friday, July 26th.

PAPILLOMA OF THE BLADDER.

MR. C. ROBERTS (Manchester), a Vice-President of the Section, occupied the chair on the third morning, when Mr. J. B. MACALPINE (Manchester) opened a discussion on papilloma of the bladder. Mr. Macalpine said that two problems presented themselves for preliminary discussion. The first, did all papillomata of the bladder become malignant? Recent literature supported the views of earlier writers that papillomata of the bladder were malignant, but this could not be entirely true, since records existed of many patients living for twenty years, and finally dying of malignant disease. The long history, however, showed that even very benign growths would eventually become malignant. The second problem was, how could the nature of the growth be decided? Pathological evidence up to the present had been misleading, and opinions still differed as to the best portion of the tumour for examination. Added to the difficulties of microscopic diagnosis were the practical difficulties of obtaining the specimen. A portion of the surface could be obtained by cystoscopy with a rongeur, but there was a very real risk of producing dissemination. The base of the tumour could be examined after open excision, but the uncertainty of the diagnosis might prevent a necessarily bold excision. For these reasons, the speaker relied solely on cystoscopic diagnosis when deciding treatment. Mr. Macalpine gave a detailed account of the cystoscopic diagnosis of the nature of papillomata. The longer and more delicate the villi the more benign was the growth; surface necrosis, uneven arrangement, coalescence of villi, and thickening of the epithelial layer giving rise to a coarser and paler appearance were indicative of malignancy. Examination of the pedicle was very important; a short, stout, stiffened pedicle was suspicious. A large villous growth completely sessile was malignant. Bullous oedema at the base should be noted, but the oedema from a previous diathermy burn should be remembered. It was only possible to distinguish these two types of oedema by repeated cystoscopy examinations. The significance of multiplicity of papillomata was debatable, but undoubtedly multiple growths recurred more readily and successive recurrences were more malignant. When in doubt concerning the nature of a growth the reaction to perurethral diathermy was of diagnostic importance. If diathermy was not definitely succeeding, partial cystectomy should be performed without any delay, since malignant tumours did not react favourably to diathermy and might possibly be stimulated by it. Cystography was of use when cystoscopy was impossible owing to bleeding, a small or intolerant bladder, or a very large growth filling the bladder. The speaker reported six cases of papilloma occurring in aniline dye workers. Before the formation of a neoplasm, there was a stage of cystitis with haematuria; cystoscopy during this prodromal stage showed a bright red mucous membrane with some mottling. The absence of exudate (as compared with the condition in septic cystitis) was characteristic. Prolonged contact with the dye was necessary before development of cystitis. Primary and secondary growths not uncommonly developed around the vesical orifice; these could be treated by means of a retrograde cystoscope, but the posterior urethroscope was sometimes necessary. Implantation papillomata from kidney and ureter occasionally occurred. The speaker gave a detailed account of the technique of bipolar diathermy. Concentration of the current on the pedicle was of great use, and the method of securing this was described. Mr. Macalpine said that growths situated high in the bladder were usually benign, but if malignancy occurred, though the growth was easily accessible by operation, late operative results were worse than in the case of growths occurring at the site of election. Excellent lantern slides were shown illustrating the various facts discussed. Mr. HENRY WADE (Edinburgh) emphasized the importance of early cystoscopy in all cases of symptomless haematuria. Fulguration was certainly indicated for the majority of growths. Situated on the bladder wall around the stalk was a roughened area, usually hidden by the growth; it was most important to treat this area also by diathermy. The speaker said that because diathermy obscured further treatment by producing a zone of reaction around the tumour, he recommended that the growth should be destroyed at one sitting under a general anaesthetic. The patient should be warned of the possibility of a secondary haemorrhage when the large slough separated. It was advisable to remove the slough to prevent formation of a concretion around it. There were four indications for open operation for an early benign growth: (1) The size; if the size of a walnut or larger he recommended open operation and diathermy. (2) The situation; collar growths around the internal meatus. (3) The clinical history. It should be remembered that vesical spasm meant infiltration. (4) Local complications, such as enlarged prostate. Endovesical diathermy in these cases had no advantages, and there was an increased risk of infection. When malignant the growth was sessile and the villi were fused and irregular. Mr. Wade said he had no knowledge of radium, therefore in these cases he practised excision. When the growth could be pulled up with a tube of mucous membrane at base, he performed a mucous resection. If there was adherence he employed a partial cystectomy. When the intravesical part of the ureter had to be sacrificed, he said that, having reconstructed the bladder, Nature produced a ureteric opening into the bladder, and the ureter could be seen later, on cystoscopy, opening into a diverticulum. The bladder should be opened first if total cystectomy had to be performed. He had found that transplantation of the ureters into the bowel was the best procedure. Early diagnosis and the education of the public was of paramount importance in the treatment of growths of the bladder.

Mr. SWIFT JOLY limited his remarks to the treatment and results of treatment of benign growths of the bladder, including growths with thick pale mucous membrane, but having no infiltration. If the growth remained superficial perurethral diathermy should be used, but the slightest indication of infiltration called for open operation and destruction of the growth by excision or deep diathermy and radium. He gave the record of 39 cases before the introduction of diathermy: there were 4 recurrences (2 early and 2 late) in 30 cases of single growths, while there was recurrence in all the 9 cases with multiple growths. From the literature he had found that 98 per cent. of sessile or multiple growths recurred. This extremely high recurrence in cases of multiple growths was a very important fact. In 25 cases with single growths treated with diathermy more than five years ago there were 6 recurrences, some being very late—14 years. All these recurrences had been destroyed and the patients remained well. Multiple growths treated by diathermy recurred, but with care and trouble an ultimate good result could be obtained by diathermy and not by open operation. Recurrences after open operation on single growths were often sessile and multiple, and he had found it impossible to get these cases clear by diathermy. From his experience he said that all cases of growths of the bladder should be kept under observation for an indefinite period, even for the rest of the patients' lives, since recurrences might become manifest at any time. The use of the various patterns of cystoscopes made growths accessible by perurethral diathermy. When the growth almost filled the bladder he used a posterior urethroscope with a continuous irrigation. Growths in the internal meatus could be treated through a posterior urethroscope, and those situated around the meatus and especially in front and at the apex of the bladder could be treated by means of a retrograde cystoscope. The use of his modification of the cystoscope enabled the treatment of growths lying behind an enlarged prostate to be carried out. The results of open diathermy were better than resection. Excellent lantern slides were shown. Mr. R. J. WILLAN (Newcastle-on-Tyne) reported an analysis of 68 cases of papillomata of the bladder. The disease was very much more common in the male—53 males, 15 females. He agreed that the pathological diagnosis of malignancy was unsatisfactory even when a portion of the pedicle was examined. The cystoscopist was sometimes misled and a benign growth

occasionally concealed a malignant ulcer. Referring to the results of treatment he said that he had not a single case alive treated more than nine years ago. An excellent analytical table was shown. The cause of death in 19 cases was given. Dissemination caused the fatal result in 6; malignant cachexia in 6; local extension to the vagina or rectum in 2; haemorrhage in 2; surgical kidney in 1; heart disease in 1; and one patient died from post-operative shock.

Professor ANDREW FULLERTON (Belfast) showed some excellent coloured drawings illustrating the technique of cystectomy. He did not like tying the ureter, and did not agree that the proximal end of the ureter should not be passed through the bladder wall and sutured as already stated. A large resection was necessary to prevent recurrence; the reconstructed bladder readily readapted itself. The troublesome bleeding from the venous plexuses at the base and posterior wall of the bladder could be much lessened by ligature of some of the larger feeding veins behind and in front. The reconstructed bladder was certainly not water-tight, and adequate drainage was important. Suprapubic drainage was not satisfactory, and his method of dependent drainage of the perivesical space by the use of a rigid tube passing downwards through the levator ani into the ischio-rectal fossa was described. He had had no trouble from this method of drainage. The best results were certainly obtained by large operations, as the glands were more easily accessible. Cystograms showing the result of large resections of the bladder were shown. This method of drainage could be used after prostatectomy. Professor Fullerton pointed out that when a growth had infiltrated the ureteric orifice, the opaque medium introduced into the bladder for cystography travelled up the ureter. A pyelogram procured by this method was shown. The disease was much more common in men, and was most frequently malignant in patients more than 60 years old. These growths recurred, whatever means of treatment was employed, and he agreed that recurrences after open operation were difficult to extirpate. Mr. H. H. RAYNER (Manchester) reported two cases of malignant diseases of the bladder treated by radium; one by the suprapubic route, and the other by a blind perurethral method.

"PARAFFINOMA" OF THE RECTUM.

Dr. A. T. BAZIN (Montreal) described a case of "paraffinoma" of the rectum resulting from the injection of melted hard paraffin for the treatment of prolapsing internal haemorrhoids. The patient was referred to him with the diagnosis of carcinoma of the rectum. At the distance of 1½ inches from the anus was a nodular mass completely encircling the bowel and producing marked stenosis; the vertical extent of the infiltration was 2¼ inches. The mucosa was smooth, mobile, and non-ulcerated. Extending distally from the constricting ring were tongue-like processes under the mucous membrane. The tumour was resected, preserving the lower end of the canal and sphincters and restoring continuity by rectorrhaphy. Another case—of paraffinoma of the thigh—was reported in a woman who had received three injections of camphor in oil as a cardiac stimulant eight years previously. Lantern slides were shown illustrating the histology of the tumour in these two cases. Dr. Bazin said that clinical observation and experimental work with monkeys had demonstrated that mineral oils, when injected, might cause foreign body reaction and tumour formation. In some cases the injected paraffin oil had spread along the lymph channels and lymph nodes, producing a condition simulating tuberculous adenitis or malignant lymphatic metastases. Vegetable oils injected experimentally had not produced these tissue masses. Mr. J. P. KILNER condemned the use of injection of paraffin into the human tissues. He had seen a large number of pathetic cases where paraffin had been injected to restore the contour of the face and neck. The histological appearances of the paraffinomata removed were similar to those demonstrated. One case of a large epithelioma which extended from the clavicles to the nipples was described; it had developed after the injection of paraffin.

CONGENITAL ARTERIO-VENOUS FISTULA.

Professor DEAN LEWIS (Baltimore) read a most learned and instructive paper on congenital arterio-venous fistula. He demonstrated his remarks with very excellent lantern slides. In this type of arterio-venous fistula, in contradistinction to the acquired type, it was of the utmost importance to ligature all the channels of communication between the artery and the vein.

SECTION OF OBSTETRICS AND GYNAECOLOGY.

Friday, July 26th.

SURGICAL TENDENCIES IN MODERN MIDWIFERY.

THE President of the Section, Professor FLETCHER SHAW, was in the chair at the final meeting of the Section, when a series of papers was read and discussed. The first communication was that of Professor ESSEN-MÖLLER (Lund, Sweden), whose subject was surgical tendencies in modern midwifery. Professor Essen-Möller asserted that surgical methods were being introduced into obstetrical practice with increasing frequency in the interests of mother and child. In cases of disproportion and of placenta praevia the old rule used to be to wait until a favourable opportunity occurred and then to assist the natural forces. The most important advance on this came about at the end of the last century with the revival of Caesarean section. The speaker had been brought up in the environment of the old ways of thinking, but his experiences had made him a convinced partisan of the newer methods. He was now afraid, however, that the pendulum had swung rather too far in the direction of operative intervention. No surgical procedure could be described as entirely harmless, but technique had now become so perfect that the risk of infection was practically non-existent. Two important considerations were: the risk of rupture of the scar in subsequent pregnancy, and the fear instilled into a mother who had undergone delivery by Caesarean section. It was not practicable to remove all cases to hospital. The speaker did not approve of Thiersch's new orientation of midwifery, which sought to substitute surgical intervention for natural labour in practically all cases. Such tendencies indicated an insufficient understanding of the normal processes of labour. Nothing great or valuable in life could be obtained except by struggle. Surgical methods were not designed to substitute and anticipate the natural forces. The PRESIDENT thought that in many ways Caesarean section had proved very disappointing. They were using it to rescue cases which they might have delivered in the old days by other methods, but they were not saving the very bad type of case. As many craniotomies were being performed now as in the past, since patients were sent into hospital too late. Dr. A. DONALD (Manchester) said that he represented the old school in some respects. In the days when he was a resident it was considered too dangerous to have cases of ordinary confinement in a hospital. Progress in obstetrics had not advanced with anything like the speed that had been experienced in gynaecology. Dr. Donald remembered the introduction of pituitrin. He imagined that this must have caused many cases of rupture of the uterus and bad tearing of the cervix and of the pelvic floor. The one line of advance had been the careful antenatal examination of cases. There had been no progress in avoiding sepsis; there was as much septicaemia as there used to be. The introduction of mercury perchloride had certainly constituted a great advance. Many students had no conception of treatment between absolute carelessness and the most up-to-date hospital methods. They ought to be instructed in the use of antiseptic procedures. Professor R. J. JOHNSTONE (Belfast) said he had been trained in the old methods, when the first maxim taught was the avoidance of "meddlesome midwifery." There was no such thing as a perfectly safe operation, and it was a serious matter to recommend surgical intervention instead of some simpler method. His experience had been that when once a patient had had Caesarean section she refused afterwards to undergo natural labour. Aseptic midwifery in the home was an impossibility; students must, therefore, learn antiseptic methods. Professor R. W. JOHNSTONE (Edinburgh)

entirely agreed with emphasizing the importance of antiseptic technique in view of the difficulties attending asepsis in the poorer homes. In domestic midwifery the use of mercurial preparations had led to a very great improvement. Weak lysol solutions were most dangerous and their employment had done much harm. In Edinburgh they were not very fond of vaginal hysterectomy; they saw a considerable number of cases of pernicious vomiting, and vaginal hysterectomy had been disastrous. Latterly they had been performing abdominal hysterectomy with very good results. Dr. Bethel Solomons (Dublin) thought there were two classes of specialists: the obstetrician, and the gynaecologist who also practised obstetrics. Obstetrics was both a science and an art, not a slap-dash surgical procedure. He thought the problem started with teaching students how to wash their hands and to put on gloves. He did not teach people to wear masks, but he taught the application of forceps without wearing a sterilized coat. Professor Miles Phillips (Sheffield) said the great difficulty in midwifery was accurate prognosis. Too many Caesarean sections were being performed owing to errors of judgement. The multipara in her twelfth or thirteenth pregnancy was not infrequently a suitable case for Caesarean section and sterilization. Professor Essen-Möller, replying, said he agreed fully with Professor Phillips that Caesarean section was applicable in many instances which could not be set out in the form of a hard-and-fast classification. He thought that the domestic circumstances in Sweden differed from those in England. Although no operation was ever performed in a patient's home in Sweden, version was employed, and forceps were applied.

Training of the Gynaecologist.

Professor T. S. Cullen (Baltimore) read a paper in which he expressed the conviction that each gynaecologist should be a surgeon capable of performing any abdominal operation. A fundamental knowledge of medicine was essential, and also a thorough grounding in general and special pathology. He gave an account of the method of training in force at the Johns Hopkins University, which aimed at the production of a man with a good knowledge of general pathology and a wide acquaintance with regional pathology. He referred to the vague and puzzling symptoms which might accompany stricture of the ureter, and which illustrated the point that every gynaecologist should also be a urologist. He gave examples of occasions on which the pelvic surgeon might have to go far afield—for example, resecting the bowel. The gynaecologist must, in short, be trained to handle any abdominal emergency which it was possible to treat. Dr. J. W. G. H. Riddel (Plymouth) remarked that all practitioners had not had the good fortune to be attached to a large teaching school. He described his own experiences, and submitted that the training of a general practitioner was by no means negligible as a branch of education in obstetrics and gynaecology. Professor R. J. Johnstone (Belfast) agreed that the gynaecologist should be capable of dealing with any condition which he might find in the abdomen. All of them were constantly meeting with surprises in their practices, and diagnoses could seldom be exact. He thought that each gynaecologist would do well to spend a year as a demonstrator of anatomy immediately after qualifying. Considerable time must be devoted to pathology. Professor Johnstone did not agree, however, that a gynaecologist should not also be an obstetrician. Professor J. P. Maxwell (Peking) thought that an obstetrician should be allowed a large working knowledge of gynaecology. He had had experience of the training in Baltimore, and he did not think that the education given in Great Britain in pathology combined with surgery was so intensive as in Baltimore. Dr. A. E. Giles praised the systematic training of Baltimore, and agreed that a sound knowledge of obstetrics was essential to a gynaecological surgeon; experience of general practice was also of very great value. The association of gynaecology with abdominal surgery was most intimate; manual skill was of less importance than sound judgement and good diagnostic ability. Professor C. G. Lowry (Belfast) thought that the intensive training in pathology was the keynote of the training at Baltimore. The President remarked that they had been made to feel the shortcomings of their own education. It was most important that great attention should be paid to the special pathology of the pelvic organs. The personality of the teacher was also a matter of considerable weight. Professor Cullen, replying, thought that anatomy should be studied by a man for himself.

A fundamental knowledge of medicine was essential. He felt very strongly that no operator had a right to open the abdomen unless he could deal with any condition he might find there.

Prophylaxis in Connexion with the Albuminuria of Pregnancy.

Mr. L. C. Rivett discussed the prophylactic treatment of cases in which albuminuria had been present in previous pregnancies. Recent work had shown that permanent renal damage resulted frequently in this way. It was important that all such patients should report at once as soon as the menstrual period was missed. It then became necessary to maintain the alkalinity of the urine at a fixed figure, and, to do this, as much as one and a half ounces of solid alkali might have to be given daily. The protein intake, including meat, milk, and eggs, should be curtailed, and milk as a beverage should be absolutely prohibited. Bread or greasy meat might be taken sparingly, however, every other day. Free daily action of the bowels should be maintained, and care taken as regards sufficient fresh air, rest, and avoidance of strenuous exertion. He cited a series of cases in illustration of these points. The President said that they had been brought up in the idea that these cases were purely functional, but recently they had become rather uneasy in their minds about the subject. Dr. James Young (Edinburgh) thought that if the facts as cited in the paper should be confirmed they must necessarily shed some new light on the etiology of the condition, and he inquired what theory underlay the line of treatment proposed. His own investigations had shown that permanent renal damage occurred in only about 8 per cent. of cases. In about 50 per cent. of the total there was evidence of recurrence in subsequent pregnancies, and in these cases there was risk of permanent damage to the cardio-renal system. The total risk of permanent damage was, however, comparatively small. The old classification would have to go by the board, since these cases showed a tendency to recur. The general rules of hygiene had doubtless a very great effect on the progress of these patients, but did not constitute the whole of the treatment. Dr. A. Crook (Norwich) said he had been giving heroic doses of sodium bicarbonate, but without much result. A considerable proportion of chronic renal cases showed no albumin in the urine during pregnancy. Dr. H. L. H. Greer (Belfast) had given alkali for heartburn, and found that there was a general improvement in the comfort and condition of his patients. In scarlet fever it had been observed that, if the urine was kept slightly alkaline, nephritis did not occur. Since he had been giving his patients alkalis he had had no case of albuminuria, even in those who had suffered with eclampsia in previous pregnancies. Other factors, such as diet, focal sepsis, and constipation, had an important bearing; the fatty substances especially should be avoided. The indiscriminate drinking of milk during pregnancy was not good; the teeth required attention, and also the tonsils and nasal sinuses; the cervix should be treated if necessary. Dr. F. H. Lacey (Manchester) said that for some time he had had the urine very carefully examined in these albuminuric cases, and he was surprised how frequently *B. coli* had been detected. The administration of alkalis in these cases was of undoubted benefit. Dr. L. C. Rivett, in replying, said that the theory underlying the treatment was the same as that in scarlatinal nephritis. He was not convinced that there was any specific toxin at the root of the trouble; he thought it was due rather to the excess of the normal products of metabolism. He had been particularly impressed by the great improvement in patients treated with alkalis. The question of focal sepsis was important, but this might occur in the absence of albuminuria.

SECTION OF DISEASES OF CHILDREN.

Friday, July 26th.

TONSILS AND ADENOIDS.

THE third morning in this Section was devoted to a discussion of the medical and surgical aspects of tonsils and adenoids, with Mr. T. TWISTINGTON HIGGINS in the chair.

The opener, Mr. J. ARNOLD JONES (Manchester), said that the function of the tonsils was still undecided; while it was probable that they were concerned with the defence of the alimentary and respiratory tracts, it was also known that when a tonsil became chronically hypertrophied or diseased it lost this defensive power. Hypertrophy of Luschka's tonsil was widespread among all climates and races, but undoubtedly adenoids were commoner in damp temperate climates. Although most prevalent between the ages of 3 and 14 years, the condition did occur in quite young babies, producing difficulties in sucking, and easily remedied by removal of the vegetations without an anaesthetic. The diagnosis of adenoids was usually easy, but the procedure of inserting a finger into the naso-pharynx was a disagreeable process and rarely necessary. In infants where the condition was suspected it was the speaker's practice to introduce a small cage curette and remove any growth that was found. In older children the only form of treatment was surgical removal. He preferred a cage curette; the commonest cause of haemorrhage was the leaving behind of a tag of adenoid tissue. It had recently been his practice to give all his patients a course of sodium bicarbonate before operation; secondary haemorrhage was rare, and out of 12,000 cases had been the cause of fatality in only two instances. Recurrence of adenoids did occur in a small percentage of cases. Mr. Arnold Jones enumerated the indications for tonsillectomy, which included interference with respiration or speech, chronic enlargement of the cervical glands, recurrent sore throats, systemic affections attributable to a focus in the tonsil, chronic lacunar tonsillitis, and diphtheria carriers. In the diagnosis of chronic sepsis in the tonsils the size of the organs was no guide; by applying pressure, pus or cheesy secretions might sometimes be squeezed out, while enlarged glands at the angle of the jaw were a useful help. Tonsil puncture was undoubtedly promising as a method of diagnosis, but Mr. Arnold Jones preferred to rely on ordinary clinical grounds. Tonsillectomy by the guillotine in expert hands was safer than dissection, and equally efficient. The deeper anaesthesia required for dissection put the operation in the ranks of the major ones, and in inefficient hands either operation might end in failure. For the guillotine operation Mr. Arnold Jones preferred Heath's type, although he had been recently trying the Popper-Heath modification. Haemorrhage was usually easily controlled by bathing the face with cold water, and occasionally a swab squeezed in hydrogen peroxide could be held in the tonsillar fossa. Beyond this it was seldom necessary to go, and it was only a tedious procedure to ligature all bleeding points. Occasionally an unusually large artery might have to be dealt with, and haemorrhage occurring a few hours after operation was sometimes troublesome. During the period 1913–28 there had only been at the most six fatalities following the operation for tonsils and adenoids at the Royal Manchester Children's Hospital; the total number of operations performed numbered 27,000. Dr. T. A. GOODFELLOW (Manchester), speaking as a general practitioner, said that diseased tonsils and adenoids were a matter of daily concern, especially where the climate was humid. He thought that more attention ought to be paid to the acute affections of these organs, for by early and prompt treatment of acute conditions there was a chance of preventing dire results. He did not agree that the diagnosis of adenoids was so easy as the opening speaker had made out, and he had been frequently struck at operations by the mass of adenoid tissue removed out of all proportion to the symptoms present. He enumerated some of the symptoms which would lead a general practitioner to suspect the presence of adenoids, and mentioned the familial incidence of the condition and its greater frequency among the Jews. He thought that there was some value in nose drill if properly carried out, especially after the adenoids had been removed. With regard to the tonsils, it was an important point to determine which cases ought to be operated on: local treatment with such substances as Mandle's paint did a lot of good sometimes, and it was his practice to allow one lapse before calling in the surgeon. He referred to the importance of suspecting diphtheria in all cases of acute tonsillitis, and ended with a strongly worded protest against the removal of tonsils and adenoids in out-patient departments. Miss G. HERZFELD (Edinburgh) discussed the relationship between the tonsils and enlarged cervical glands. She had analysed a large number of cases of tuberculous cervical glands, including nearly 700 cases on which she had operated. She found that in 95 per cent. of cases it was the tonsillar gland which was primarily involved, and yet on inspection the tonsils often appeared healthy and not markedly enlarged. Examination of tonsils removed in such cases showed evidence of tuberculosis in a varying percentage of cases, and out of a recent series of seventeen cases *tuberculous tonsils had been found in nine.* Removal of the tonsils in early childhood seemed to prevent the development of tuberculous cervical glands in later life, but if the glands were already involved it was doubtful whether tonsillectomy ever cured the condition. Miss Herzfeld mentioned other surgical conditions for which tonsillectomy was indicated, including the presence of pneumococcal infections of bones and joints. She mentioned the association of adenoids and flat feet in the same type of child, and concluded by referring to the psychological shock of the closed bag type of anaesthesia.

Dr. D. NABARRO reported some work by Dr. R. A. MacDonald at the Hospital for Sick Children, Great Ormond Street, on the bacteriology of the tonsils in relation to rheumatism in children. It had often been suggested, he said, that the infective agent in this condition was to be found in the tonsils, and especially the streptococcus had been blamed. It ought therefore to be possible to find a bacteriological flora in the rheumatic type of child different from that in the tonsils of the non-rheumatic, and for this purpose a series of 50 rheumatic tonsils and 48 non-rheumatic tonsils had been investigated, and all varieties of streptococci present isolated. The results showed, however, that the tonsils from rheumatic patients did not differ materially from those of non-rheumatic cases as regards the characteristics investigated: actually the percentage of "inert" streptococci was slightly lower in the rheumatic group. Dr. Nabarro summarized the work which had previously been done on this aspect of the subject, and indicated that modern theories inclined to some hypersensitive state as a cause of rheumatism rather than an ordinary streptococcal infection. Dr. JEFFREY RAMSAY (Blackburn) referred to the work of himself and Mr. C. M. Pearce on the use of tonsil puncture for assessing the state of the doubtful tonsil. He mentioned the reasons for adopting the procedure, and described briefly the technique employed. In two cases of Henoch's purpura recently examined by means of tonsil puncture a pure growth of *Streptococcus pyogenes* was obtained and tonsillectomy led to great benefit. In the diphtheria carrier it was possible that infection lurked deep in the tonsils; it was also possible that in lobar pneumonia the organism might be present in the tonsil, as had happened in a recent case some eight weeks after the crisis. Dr. FRANK C. EVE (Hull) explained the method of tonsil suction by a simple instrument introduced by himself consisting of a glass funnel and tube and a strong rubber suction ball. Pus could be obtained for diagnostic purposes from the tonsil by this apparatus, and application of medicaments on to the everted tonsil could also be carried out by slipping a finger-stall over a similar instrument. The cleaning up of diseased tonsils before tonsillectomy by this means was important and might prevent haemorrhage. Mr. DENIS BROWNE said that the functions of the tonsils and adenoids were completely unknown, and he pleaded for some straight thinking on the matter. For the removal of adenoids he used a form of guillotine which cut from below upwards, and he showed how the ordinary curette, besides being often too big, was also liable to produce ripping of the pharyngeal wall, especially under light anaesthesia, which allowed "gagging." With regard

to removal of the tonsils, he made a spirited attack on the guillotine, enumerating certain elementary surgical principles which its use violated. He looked upon the leaving of a piece of tonsil behind as a surgical disaster likely to do the patient harm, and he particularly stressed the loss of blood which occurred when methods other than dissection were used. Mr. F. HOLT DIGGLE (Manchester) commented on the use of the finger for examining the nasopharynx, and explained that he preferred to rely on clinical examination of the child and a consideration of the symptoms. He discussed the recurrence of adenoids, and said that there ought to be a more careful scrutiny of the child before removing various portions of hypertrophied lymphoid tissue. It was his experience that enlarged tonsils and adenoids not infrequently disappeared while the patient was awaiting admission to hospital. It was important to ask in every case, Was the tonsil diseased? Was it the source of infection? and Was it the only source of infection? He emphasized the point that the slow, deliberate guillotine operation under a long anaesthesia met many of the objections raised to this form of tonsillectomy. Dr. H. BRACEY (North Warwickshire) discussed some of the aspects of tonsils and adenoids which came under his consideration. He mentioned the importance of the general type of child who had tonsillar hypertrophy as part of a general defect. Dr. ESTHER L. CARLING (Oxford) drew attention to the potentially tuberculous child whose main trouble was frequently throat affections. She emphasized the dangers of operations performed in out-patient departments. Dr. C. P. LARAGE (President) agreed as to the connexion between flat feet and enlarged tonsils. He emphasized the importance of the toxaemia that arose from diseased tonsils, and explained how it might simulate tuberculosis. Dr. H. T. ASHBY (Manchester) said that beneficial effects of removal of tonsils and adenoids could only be expected if the proper cases were selected, and he insisted that a skilled operator was essential. Professor C. W. VINING (Leeds) had not found that tonsillectomy benefited cases of rheumatism, and he had not noticed the increase in weight after the operation which some other observers had reported. Dr. R. SCOTT STEVENSON said that the present method of removing tonsils and adenoids in the out-patient department of hospitals was a disgrace to British surgery. After some further discussion it was unanimously agreed that the following resolution should be sent to the Council of the British Medical Association:

> That this Section of Children's Diseases is of the opinion that operations for removal of the tonsils and adenoids in a child should not be carried out as an out-patient operation; and that provision should be made by hospital authorities and local authorities for children to be kept in bed under observation for at least forty-eight hours after operation.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Thursday, July 25th.

THE PRESENT POSITION OF THE VOLUNTARY BOARDER.

THE second session of this Section was devoted to consideration of the problems presented by the voluntary boarder in mental hospitals. Dr. HENRY YELLOWLEES, who opened the discussion, said that in this country there were three classes of "mental" institutions: the county or borough establishments for rate-supported patients, the privately owned "licensed houses," and the registered mental hospitals. In addition to rate-aided patients, many of the county asylums were allowed to admit paying patients at a low figure, but no patient could enter these institutions unless he had been certified and a magistrate's order obtained. This was probably the greatest blot on the present lunacy administration. The licensed houses and the registered hospitals only received voluntary boarders. A voluntary boarder was a person who entered the institution on his own request, and was free to leave it at twenty-four hours' notice should he desire to do so; expressed willingness to remain was the sole criterion of such a patient's suitability to stay in a mental hospital. There was no more pitiable *reductio ad absurdum* than this, that the deciding factor as to a person's legal sanity was simply whether he could express a desire to remain in hospital. Another important question was that of the patient who, having entered a mental hospital of his own accord, became, owing to illness, incapable of expressing his wishes. This problem of the non-volitional case had always been the centre of controversy, and had led to the criticism that if a patient, fearing a mental breakdown, entered a mental hospital, he would not be permitted to remain when the very illness for which he sought care supervened, should it render him incapable of expressing his wishes. The Lunacy Act regarded voluntary boarders purely from the point of view of the liberty of the subject. It looked on them as persons who, having taken the risk of jeopardizing their personal liberty, must be safeguarded from any unscrupulous persons who might attempt to take advantage of this fact. The conception of a voluntary boarder as a sufferer seeking advice, treatment, and care in a hospital was utterly foreign to the Act. The unenviable task of interpreting and administering the law as to voluntary boarders fell on the Board of Control, and the result was a reasonably broad and common-sense interpretation. The Board did all it properly could to avoid or postpone the certification or removal of the non-volitional case. When there was some ground for expecting return of volition in a reasonable period, a week or two's grace was usually granted, particularly when the relatives urgently desired it. The crux of the whole matter was that the non-volitional patient could not legally remain in a mental hospital; the problem had so far proved insoluble, and seemed likely to remain so until the public view of mental disorder and its treatment had been re-educated and the law entirely recast. Assuming that care and treatment at home were impracticable, there was no alternative to certification, but two other possibilities might be legalized, the first being treatment of such patients in a nursing home, "free from the taint of lunacy." Dr. Yellowlees mentioned this course only to condemn it. Secondly, it might be made legal to retain uncertified in the mental hospital a voluntary boarder who had become non-volitional. This was the ideal arrangement, but it was difficult to see how it could be brought about. In the present state of public opinion, Dr. Yellowlees could imagine no workable system of "safeguards" which would be likely to meet with general acceptance. Provisional certification was a clumsy compromise which would probably have been unworkable, and in any case did not meet the difficulty. As things were, however, there was no alternative to certification if the voluntary boarder who had become non-volitional was to remain in a mental hospital. One practical difficulty immediately presented itself. The patient became certifiable; his relatives wished him to remain in hospital and were agreed that he should be certified. Was it fair to proceed with this and retain him as a certified patient? A majority of the public regarded this procedure as a gross breach of faith in the case of a patient who wished to leave, and many mental hospitals refused to keep as certified those who had been with them as voluntary boarders. Certification, though distasteful, would remain necessary until there was a more satisfactory alternative, and until the problem of the non-volitional case had been solved. There was much to be said in favour of certification in many cases, even under the existing law, and most of the public horror of it was the result of ignorance and prejudice. The extraordinary variety in the symptoms and needs of the patients admitted to a central hospital of any size, along with the constant dead weight of irrecoverable chronic cases, presented a problem which needed—among many other things—almost unlimited space, staff, and money for its solution. Dr. Yellowlees had long thought that the chronic, unpleasant, and noisy cases should be removed to completely separate and independent branches of the mental hospital.

Professor GEORGE M. ROBERTSON (Edinburgh) said that the Scottish Lunacy Act, though passed so long ago as 1857, was inspired by a medical spirit that seemed surprising for that period. The experiment of treating voluntarily patients suffering from mental disorders was first tried in Scotland in 1862. The voluntary patients who were

admitted to mental hospitals in Scotland under the 1862 Act were all of unsound mind. Any person could be admitted as a voluntary patient provided he made a written application to that effect. After admission to a mental hospital he might continue to enjoy the status of a voluntary patient, so long as he lived or until he gave notice of desire to leave. Since Scotland enjoyed such exceptional facilities in law for voluntary treatment, and possessed extensive resources in accommodation for private patients at moderate rates, the number of voluntary admissions of this class was very large, and far exceeded the number of those who were certified; 60 per cent. of all the private patients entering the mental hospitals in Scotland did so as voluntary patients, and in some hospitals among the richer classes this percentage was exceeded. If this was taken in association with the fact that a large number of persons suffering from mental disorder were also treated without certification in nursing homes in Scotland, it was obvious that the great majority of persons of the richer classes in England who suffered from mental illness were not certified. There were two great differences between the English and Scottish lunacy laws relating to voluntary patients. (1) *According to the strict interpretation of the* English law, a person of unsound mind, one who could be *certified, could not legally become a voluntary boarder; or*, after he had become one, could not remain so. Although in practice this law was not now strictly administered, nevertheless the legal difficulty existed and frequently created anxious problems. No such difficulty existed in Scotland, and the question whether the voluntary patient was of sound or of unsound mind did not arise. Only one condition need be fulfilled for becoming a voluntary patient in Scotland—namely, a written application expressing a desire to submit to treatment. The presence or absence of sanity was not a condition. (2) A voluntary boarder might only remain as such in England so long as he was definitely desirous of remaining so; in Scotland in these circumstances the patient would not be certified. There was only one condition that normally put an end to the status of a voluntary patient, and that was when the patient himself gave notice of his desire to leave. The onus of taking action to terminate the voluntary status was very appropriately placed on the patient himself, and the procedure had to be initiated by a definite and unmistakable signal. The problem of the non-volitional case was of two kinds: (1) the patient already in a mental hospital as a voluntary boarder, and (2) the patient at home. (1) A voluntary boarder who became non-volitional could not remain as such in a mental hospital in England; in Scotland he could, so long as no notice of his intention or desire to leave had been given. As the question of the soundness or unsoundness of mind of a voluntary patient did not arise in Scotland, the problem of the non-volitional case was so far simplified. It seemed a work of supererogation to certify a patient for reception and detention in a mental hospital who had already been legally received and was undergoing treatment there. (2) For over eighty years it had been legal in Scotland to treat a patient suffering from mental disorder, with a view to his recovery, in any house or home, without certifying him to be insane. The authority for this was the well-known "Schedule G," and its provisions had been more or less closely followed in bill after bill for England, none of which had, however, passed into Acts. This schedule undoubtedly influenced the views of the Royal Commission. As regarded treatment in nursing homes the speaker agreed with Dr. Yellowlees, provided that he had referred to ordinary nursing homes in England. A very different situation existed when a public corporation, with a disinterested board of managers, with a century of experience behind it and with unbounded resources, provided special nursing homes for mental patients. Professor Robertson had no hesitation in saying that at present such nursing homes were the very last word in the treatment of non-volitional cases of mental disease, without certification. The managers of the Royal Edinburgh Hospital at Morningside had established six associated nursing homes for nervous and mental patients. These admitted about 150 patients a year; they had a resident population of about seventy-five, and they had a staff of nearly ninety nurses. The demand for admission from all parts of Great Britain was so great that all these homes were full, and three more were about to be opened. The whole resources and experience of the Royal Edinburgh Hospital were placed at the disposal of these associated homes, and they appeared to be the ideal form of care for non-volitional patients, suffering from mental disease, whom it was not desired to certify. The treatment of the poor, especially of the rate-aided poor, had not kept pace with this progress. There had been legal difficulties in the way, just as in England. By the repeal of the provisions of Section 64 of the 1913 Lunacy Act (the Local Government (Scotland) Act), these legal difficulties had now been swept away, and there was nothing to prevent the rate-aided poor from enjoying in the future all the advantages of voluntary treatment that the rich had had in the past.

Sir C. HUBERT BOND thought that much confusion had arisen on the subject of the voluntary boarder owing to the wrong way in which the term "voluntary" was used—namely, the habit of regarding it as synonymous with early, mild, and recoverable, and applying it to such cases. Moreover, the continued use of the term "boarder" was misleading. Originally, it was meant to apply only to (1) those patients who had previously been under certificate, and who wished to re-enter the mental hospital *voluntarily; and (2) relatives of patients who desired to* stay as boarders in the asylum. The crux of the problem, however, was that the so-called voluntary patient might pass into a stage that had been termed "involuntary" or "non-volitional." The speaker did not look upon these terms with favour, and, moreover, the public did not understand them. As regards their attitude to treatment, he would prefer to place patients into one of three classes: willing, indifferent, or unwilling. Alterations in the existing Act were certainly desirable, but in order that they might be brought about it was necessary, in the words of the late Sir Clifford Allbutt, "that the static mind of the lawyer come to terms with the dynamic mind of the biologist." Sir Hubert Bond considered that it was impossible to do without certification. He hoped it would be retained for those patients who could not perceive that they were mentally ill, and also to protect people who had to meet those often hostile and dangerous patients—the "unwilling" class. Dr. E. MAPOTHER said that, in addition to the voluntary boarders in registered hospitals and licensed houses, there were two other groups which were very important, not only at present, but, owing to their significance, in the future. Into the Maudsley Hospital were admitted every year half as many voluntary boarders as into the sixty private institutions. In the City of London Mental Hospital there was a large group of voluntary boarders. Though these patients were not supported at public cost, they were probably more like those who would be so supported in the other public hospitals (when such expenditure is legalized) than any in the private institutions or the Maudsley Hospital. Dr. Mapother contended that so far as difficulties existed for the public mental hospital they were financial, and as regards the private mental institutions, they were not now, and had not been, in the law, but in the practice of the Board of Control. This was entirely at variance with Dr. Yellowlees's view, but it was the fact. The Board had persistently obstructed and restricted voluntary treatment. The law, in permitting this for the recurrent case, had obviously intended permission to continue when certifiable. The Board had not only insisted on certification, where possible, in the recurrent case, but opposed voluntary treatment in all but the recurrent case. In his view there was nothing in the law to prevent continued treatment as voluntary boarders of either certifiable or non-volitional patients. This view was strengthened by the fact that such a regime had been approved by the Board and in force for six years at the Maudsley Hospital. Elsewhere the Board was only slowly being forced by pressure of outside opinion into action upon the two logical principles: that the sole criterion of fitness to be a voluntary boarder is willingness, and the sole criterion of willingness is the last expressed wish of the patient. The moral was that, *before* the really essential changes in law, such as financial provision for voluntary patients in public hospitals, there was necessary a change in the connexion in the policy and in the personnel of the

Board. This was almost vital in order to ensure that the great influence of the Board in framing the law was used in the right direction. If such reconstitution of the Board was really impossible, then it should take representative opinion before using its influence. Dr. HELEN BOYLE (Brighton), speaking as a member of the National Council for Mental Hygiene, felt profoundly dissatisfied with the present position of the voluntary boarder. Excepting a few cases in London, it was a provision only for the well-to-do and the rich; it was entirely unattainable for the poor, for whom it was far more essential. It had been said that it was pushing at an open door to demand this amendment. Each Government, and every body of persons concerned, agreed to and approved this provision for the last twenty-five years and more. The speaker could not help thinking that the door was transparent, but not yet open, and that the glass which barred them out had a metal in it. So good were the present mental hospitals that it was thought that they would be besieged by those impecunious members of the public who would prefer ease to work. Surely, if discretion was given to the medical superintendent, it was a reflection upon him if he could not separate the sheep from the goats. In time, probably most mental patients would be voluntary boarders. In America there were far more voluntary boarders than certified patients. Now was the time to push open the door. There was reason to suppose that the Government would certainly not be uninterested in the provision of help for the most unfortunate of mankind.

Dr. R. EAGER (Exeter) said that it was surely time that these laws were altered so as to allow the same facilities to the rate-supported class as now only pertained to private patients. The present lunacy laws were framed in 1890, and were now sadly in need of revision, yet years went on and nothing seemed to be done in this matter. When the present laws were made it was evident that the sole idea in the minds of those who framed them was one of detention, and that this was thought necessary, on the one hand, to guard the patients against ill treatment by their relatives and those outside mental hospitals who did not understand them, as well as, on the other hand, to protect the public from homicidal attacks and other risks of disturbance to which some cases of mental disorder were prone. The idea of treatment, however, was not to be gathered from reading the Lunacy Act from beginning to end; in these days, when so much was being done in mental hospitals in this country to try to restore patients to health and discharge them back to their homes, it seemed that it was quite time for something to be done to make the law in this matter meet modern progress. It could not be claimed that the private mental hospitals in this country had any better provision for the treatment of cases of mental disorders in their early stages than the county or borough mental hospitals; indeed, it was improbable that many of them had as good equipment for the treatment of patients as had the public mental hospitals, and yet these were the very institutions that were forbidden to treat early cases which were wishful to obtain that treatment. He had had patients come to him and ask for admission who were, even on superficial examination, obviously suffering from early symptoms of mental disorder, and he had to refuse them. Also one had to tell them to wait till their symptoms were so bad as to be easily recognized, not only by the general practitioner, but by a magistrate, who need not be, and usually was not, a medical man. He sincerely hoped that the outcome of this discussion would be that some alterations would be quickly made to right this wrong. Dr. W. A. POTTS (Birmingham) said the opener of the discussion had raised the question, Why could not the mental case be certified and removed as a matter of course like a small-pox patient? His feeling was that there must be much education, not only of the public, but also of the medical profession, before this would be possible. The small-pox patient was told that, through no fault on his part, he had caught an infection dangerous to himself and others. But his experience was that the majority of the nervous or early mental cases had been told one of two things—either that there was nothing wrong with them, or that, if there was, it was their own fault for worrying and having such silly ideas. It was unusual for the patient to be told, as he should be, that he was either suffering from some chronic infection or, if thorough investigation showed there was nothing of that kind, that he must have some form of mental conflict, which was not his fault, but the inevitable consequence of an unsatisfactory environment in his home or school, or during some other important period of his life. As regards the statement that there was nowhere where the poor could go for satisfactory treatment, he knew that if they lived in West Bromwich they could go to Hallam Hospital, and would be welcomed there at any stage of their illness. So far from a mental hospital being the only suitable place for treatment, the fact was that the general hospital had many advantages, such as specialists in other departments, but, above all, the fact that it was happier for the patient to be treated just like any other patient, while it made nurses and junior medical assistants realize that the treatment of nervous and mental cases was just one province of general medicine, and not an occult science to be practised in a place apart.

Dr. F. E. FREMANTLE, M.P., was quite sure that there was not a single member of Parliament who did not sympathize with the difficulties regarding the voluntary boarder and early mental case. It was essential that the public should be made to realize what was wrong—and also *their representatives in Parliament*. Medical men should give more time to bringing the matter to the relatively uninstructed and static mind of the lawyer; the same applied to most members of Parliament. It was essential to try and get the Government to include the necessary legislation as part of their programme, and so bring about a much-needed reform. Dr. C. A. MORTLOCK-BROWN (Braunton) said that three classifications had emerged: (1) the legal one of "certifiable" and "non-certifiable"; (2) that recommended by the Board of Control to the Royal Commission of voluntary, non-volitional, and unwilling; and (3) noisy and quiet patients. The legal classification was a more or less practicable working one, and if the other classifications were adopted, would it really be any easier to forecast whether at a given time in the future a patient would be willing or noisy, than it now was to decide whether he would be certifiable? She saw no reason why non-certifiable cases could not be treated in institutions separated in every way from asylums. She did not wish it thought for a moment that she was averse to the total abolition of certification, but notification by name and address was a similar stigma, and in the three-fold stigma—the nature of the illness itself, residence in a mental hospital, and certification—enveloping the patient, certification was the minimum factor. Whereas both relatives and friends knew of the patient's being "put away," it was not until recently, when certification had been advertised in the press by the medical profession, that anyone but the immediate relatives knew or understood anything about certification. There were now on the Board of Control five medical men commissioners, one being honorary, and four medical men inspectors—in all nine medical men—but not one medical woman, and this despite the fact that for four successive years the number of females certified insane exceeded the number of males by 12 per cent. She appealed to Dr. Fremantle to use his influence to get two medical woman commissioners appointed forthwith—one honorary and one salaried.

FRONTAL LOBE TUMOURS.

The difficult problem of diagnosing and localizing tumours in the frontal lobes was the subject of a discussion on the third day of this Section. The discussion was opened by Dr. JAMES COLLIER, whose paper is published in full at page 289.

Dr. W. J. ADIE said that the "grasping reflex" had been of value in localizing tumours of the opposite frontal lobe. The fully developed reflex was very striking, but it also appeared in various incomplete forms; hence the term "grasping reflex" did not cover the entire phenomenon. In his opinion it was not necessarily confined to extensive lesions. The fits seen in frontal lobe tumours might consist of some movement of the head, eyes, and trunk to the opposite side, with simultaneous involvement of the limbs

of the contralateral side. Such an attack, however, might also occur in temporal lobe tumours. A fit beginning with clonic movements of the eyes with deviation to the opposite side was of localizing value in frontal lobe tumour; in fact, such movements might constitute the entire fit. Mayer's reflex was of great value, a unilateral exaggeration being a lateralizer to the opposite side and a localizer to the opposite frontal lobe. Homolateral hemiplegia appeared to be particularly common in endotheliomata of the frontal lobe, and Dr. Adie described cases illustrating this point. He thought ventriculography was especially valuable in frontal lobe tumours. Mr. GEOFFREY JEFFERSON (Manchester) considered that ventriculography could be well replaced by the method of "ventricular estimation." This consisted in the bilateral tapping of the ventricles by the occipital route, the withdrawal of cerebro-spinal fluid from each, and the comparison of the volume of the two samples of fluid. He had not found the injection of dyes of great value. Mr. Jefferson then described certain cases of frontal lobe tumour which he had encountered, and illustrated his cases with admirable lantern slides. Dr. L. J. J. MUSKENS (Amsterdam) said that he had met with a case showing the sudden occurrence of status epilepticus, without previous symptoms, in frontal tumour. Differential diagnosis from general paresis was sometimes difficult, particularly since general paresis was changing in character, cases of excitement becoming rarer. Bruns had called attention to ataxia and vestibular symptoms in frontal tumours. In 1917 the speaker had pointed out that cats, after an extensive frontal lesion on the right side, and also persons suffering from right frontal tumour, tended to fall to the left; in supratentorial tumours use might be made of this lateralizing symptom. This observation was confirmed by Grosmann in 1919, who described six cases of frontal lesion from bullet wounds; in every one of these cases the patient fell to the contralateral side. Dr. C. WORSTER-DROUGHT thought that mental symptoms were more frequent in frontal lobe tumours than in those affecting other regions of the brain. In his experience the mental symptoms associated with right-sided lesions were slighter than those accompanying left-sided lesions; the former might consist of mere memory defects, while the latter varied from euphoria to dementia. He agreed that involvement of the white matter of the brain was the important determining factor. Tremor he had found of no assistance, but the "grasping reflex" was a valuable sign when present; it was, however, often absent. Incontinence was a very frequent sign of frontal lobe tumour, and might be the only symptom present, or occur with only slight mental dullness. The absence of the epigastric and abdominal reflex on the homolateral side was also helpful. He had been impressed with the frequent absence of headache in cases of frontal tumour he had seen. The presence of papilloedema was very variable, and, he agreed, could not be relied upon, either for localization or for lateralization. Air ventriculography was of considerable assistance, but he had come to regard the procedure somewhat risky in posteriorly situated tumours; he was, therefore, glad to have heard Mr. Jefferson's opinion regarding the value of ventricular estimation. Dr. J. GODWIN GREENFIELD commented on the extraordinarily long history and the hardness of the tumour often met with in the astrocytoma type of frontal glioma. There was a greater tendency to degeneration and cyst formation in frontal lobe tumours; this probably resulted from some peculiarity of the blood supply. Dr. MACDONALD CRITCHLEY stated that the phenomenon described by Adie and himself as "forced grasping and groping" had been originally reported by Janischewsky as the "réflexe de la préhension." The phenomenon was made up of several component parts. First, it comprised a slow and gentle flexion movement of the fingers on appropriate stimulation of the palm. The optimum stimulus was a moving contact on the base of the fingers and ball of the thumb. The second phase consisted in a forceful and involuntary closure of the fingers when the examiner attempted to withdraw an object from the patient's hand. The involuntary nature of the inability to relax the grasp was shown by the fact that a painful stimulus—such as a live electrode—still elicited an identical firm closure of the hand. After the object had finally been extracted from the patient's hand the third part of the phenomenon became manifested by a slow, full extension of the fingers, followed by a slight closure. In this way the patient's hand might close again on the object which had just been released ("after-grasping"). In some cases a fourth set of phenomena was seen; if the examiner was attending to some other part of the anatomy, the patient's affected hand frequently "butted in" and obtruded itself by clasping the examiner's hand. Or it might be possible to get the patient to follow one's hand with his eyes shut by merely lightly touching the finger-tips. Each contact caused the patient to grope towards the examiner's hand ("forced groping"). In cases in which there was some impairment of mentation a feature may be noticeable, spoken of by Schuster and others as the "grasping affinity." Thus it might be observed that the patient's hand was always clutching an object—the lapel of the coat, or the bedclothes—as though the patient were unwilling to have his hand empty. In other cases, also, it might be noted that as soon as the physician entered the room or approached the bed, the patient's hand was extended like a tentacle in an effort to clutch the physician as he passed. It was now realized that the grasping phenomenon might appear in regions other than the hand. Thus it had been observed in the sole of the foot; Janischewsky had recently described a similar concomitant inability to relax in the jaw, so that an object placed between the teeth could not be released ("the bulldog phenomenon"). Although forced grasping and groping might be seen in various states of stupor and coma and in some instances of diffuse cerebro-vascular disease, its presence in cases of cerebral tumour usually indicated a frontal localization. Although of high localizing value, its importance as a lateralizing sign required some qualification. Thus, Dr. Critchley had seen two cases—and Schuster had also reported one—in which the grasping phenomena had occurred on the same side as the tumour. In these instances, however, there had been a severe degree of hemiplegia on the contralateral side, with the presence of ipsolateral slight psychomotor abnormalities such as the grasping reflex. Presumably the tumours were large ones in such cases, and were capable of producing bilateral signs. Dr. F. R. FERGUSON emphasized the importance of investigating all possible channels of information—a full detailed history, the careful examination of the patient, and the employment of ventriculography and ventricular puncture in suitable cases. In some cases daily physical examination revealed such variation in the physical signs that it was impossible to correlate them and localize the tumour; this was especially marked in cases seen some time after the onset. A patient presenting clinically a marked right-sided "frontal tremor," but with other signs at one time indicating a left-sided frontal lesion and at other times a right-sided, was proved at the necropsy to have a cholesteatoma situated exactly in the middle line at the posterior end of the corpus callosum. With regard to the localizing value of the "grasp reflex," he drew attention to a case at the National Hospital, Queen Square, with a right-sided grasp reflex; a left cerebellar tumour was found at autopsy. In this patient the cerebration and co-operation were very poor, and there was evidence of secondary hydrocephalus. Dr. Collier had said, in reference to the occurrence of mental symptoms in frontal tumours, that they were almost invariably present in bilateral frontal neoplasms. Dr. Ferguson had observed a patient with bilateral frontal metastatic deposits in addition to twelve other intracranial tumours, who did not show any abnormal mental symptoms ten days before death; despite the fact that Globus and Selinsky and Siefert had described a syndrome characteristic of metastatic deposits in which psychological abnormalities played an important part. Dr. A. A. MCCONNELL (Dublin) considered that ventricular estimation was of more value in the lateralization of a tumour than in localization, and especially in the case of frontal lobe tumours. One fallacy, however, was that a frontal tumour might cause occlusion of the foramen of Monro and so prevent the injected air from reaching the opposite ventricle. Dr. McConnell also dealt with the displacement of the ventricular cavities seen in ventriculograms.

SECTION OF DERMATOLOGY.

Friday, July 26th.

THE EPIDERMOMYCOSES.

DR. G. H. LANCASHIRE, President of the Section, took the chair at the second session, when three papers were read. Dr. G. B. DOWLING gave an account of epidermal infections with yeast-like organisms, and made special reference to the spore of Malassez. He said that, during the last few years, considerable additions had been made to their knowledge of pathogenic yeasts. All the epidermomycoses were due to one family—the Oösporaceae—which resembled ordinary yeast in many ways, but were of simpler reproductive habits and also produced a mycelium. They were also very pleomorphic. From the pathological point of view the most important genus was monilia, of which the chief species was *M. albicans*, the organism that caused thrush. Clinically, scales from the lesions on the skin caused by monilia showed long, thin mycelia, with lateral thallospores. As a rule, it affected skin folds only, but when warmth and moisture were provided it might spread on to wider surfaces. There were six main types of infection: (1) generalized cases occurring in those subject to continuous water bath therapy; (2) cases in nursing infants; (3) intertriginous cases; (4) paronychia; (5) infections of the nail; and (6) dysidrosiform infections. In all cases the site of maximum infection was marked by a whitish accumulation of epithelium. Both intertriginous eruptions, paronychia, and dysidrosis were quite commonly caused by monilia. Dr. Dowling then proceeded to discuss the role of the spore of Malassez in dermatology. He pointed out that this organism, of which the forms were very varied, was always found in scales from the scalp. Many attempts had been made to cultivate it, and the first success had been claimed by W. G. Garner (1908); his work had been confirmed by MacLeod and the speaker in 1926. Benedek had also claimed to cultivate it in 1926; he stated that it was an ascomycete, and named it schizosaccharomyces, ascribing to it many dermatoses, including seborrhoea itself, pityriasis of the scalp, and acne. He had also been able occasionally to recover it from the blood, and had made very comprehensive and far-reaching claims for his organism, the characteristics of which, however, were quite different from that grown by Garner. Acton and Panja, in India, claimed to have cultivated the spore of Malassez on Petroff's medium as dry, white, chalky colonies, but their work was incomplete. Templeton also seemed to have done much the same. During 1927 and 1928 the speaker and Dr. MacLeod had published some observations on the organism cultivated by Garner's methods, principally on maltose agar. The organism was pleomorphic: it produced mycelial filaments, and fermented many sugars. When inoculated intradermically it was always pathogenic, giving rise in normal individuals to temporary follicular lesions only, but in seborrhoeic subjects to similar lesions which were rather more active and lasting; in those suffering from seborrhoeic dermatitis the lesions were often absolutely identical with those already present. Hence it was concluded that Garner's organism was, in fact, the spore of Malassez, and that this fungus alone was probably responsible for seborrhoeic dermatitis. Recently Dr. Dowling had also found that exactly similar lesions could also be produced by the inoculation of monilia. He thought there was no doubt that the spore of Malassez was a member of the monilia group. The PRESIDENT said that this was a most important and valuable paper, and a solid contribution to dermatology. Dr. ROXBURGH stated that in the treatment of monilia affections he had found prolonged soaking in iodine and water most useful. Sir NORMAN WALKER (Edinburgh) remarked that Unna's original ideas were now, after a lapse of time, being confirmed.

TREATMENT OF LUPUS VULGARIS.

Dr. A. R. HALLAM (Sheffield), in a paper on the early and organized treatment of lupus vulgaris, said that this was a common disease essentially associated with poverty, which was a grave drawback to its successful treatment. He emphasized the enormous time and trouble required in dealing with it. It was not a superficial, but a constitutional disease, for which no single remedy was adequate, and which few practitioners were sufficiently expert to treat. Besides a dermatologist other specialists were also required; for example, mucous membrane lesions were common, but often overlooked, to remain a source of danger unless the cases were submitted to a competent rhinological examination. Excision was extremely valuable in the early stages, but needed an experienced surgeon; in advanced cases this was impossible, and one had then to fall back on various measures, such as diathermy, caustics, and actinotherapy. The speaker regarded the Finsen light as very valuable, but said that it should be associated with the carbon arc as an auxiliary; the latter alone was quite insufficient. When available in summer time natural sunlight was still more effective. One of the greatest difficulties was the fact that the patients only came to seek expert advice when the disease was far advanced. Of 138 cases 34 alone were in such a stage as to offer a reasonable hope of cure, while in 85 the prognosis was very doubtful, and 19 were hopeless; 53 patients had had the disease ten years before they had applied for expert treatment. He held that all cases should have at their disposal the best treatment available, which fell into four categories: (1) prophylaxis; (2) education both of the medical profession and the public; (3) establishment of *treatment centres; and (4) the systematic following up* of cases. All senior medical students should be taught to recognize the disease in its early stages. Centres such as the Finsen Institute at Copenhagen would be of great value, not only to the patients actually treated there, but as a stimulus to other medical men. The PRESIDENT commended this very practical and apposite paper. He thought that on the whole the early diagnosis of lupus was much better now than formerly; one saw the severer forms of the disease much less often. Nevertheless, of course, there was much room for advance. Dr. P. B. MUMFORD (Manchester) supported Dr. Hallam's suggestion for the specialization of lupus treatment and the establishment of lupus clinics. Sir ROBERT BOLAM (Newcastle) said that in Durham much had been done by the county council to organize the control of surgical tuberculosis, including lupus, on sound lines in association with the tuberculosis officers and with hospitals specially qualified and equipped to deal with these cases. The county council paid for the work done, and the medical men employed received some remuneration. The scheme had been established about two years, and was working successfully. Sir NORMAN WALKER agreed with Dr. Hallam; special lupus clinics should be held. The sight of the advanced cases acted as a warning against neglect to the early ones. Local authorities were most helpful. Dr. L. SAVATARD (Manchester) remarked that the local authorities in the neighbourhood of Manchester were also anxious to do all they could to assist these sufferers. Medical practitioners still needed education in the early diagnosis of the disease. Dr. GARDINER (Edinburgh) said that in some cases the local authorities were to blame in taking away the cases from expert treatment, and in treating them blindly by light.

SYCOSIS BARBAE.

Dr. J. T. INGRAM (Leeds) read a paper on sycosis barbae, and reminded the meeting that Sabouraud had called this disease a disgrace to dermatology. Pathologically the condition was an external infection of the hair follicles of the adult beard with the staphylococcus, accompanied by surrounding hyperaemia. He distinguished it from seborrhoeic dermatitis of the same region, which never affected the beard alone. Sycosis was almost exclusively seen in the hospital type of patient, and he thought that the reason was that they shaved irregularly. He considered that he had had better results than the average in this disease (he had cured 11 out of 14 cases during a year) because he had studiously avoided the use of ointments, preferring strong antiseptic lotions, and had advocated regularly daily shaving by the patients. The prognosis of cases treated on such lines was, he believed, quite good. Dr. R. GIBSON (Manchester) believed that there was often a constitutional factor; he had found sea air useful in raising

the level of the patient's resistance to bacterial infection. He did not believe much in regular shaving, and thought that strong applications irritated the skin. Sir ROBERT BOLAM ... many of the worst cases were due to measles in early life; no less than 70 per cent. of the bad cases had such a history. Dr. SAVATARD asserted that the lower eyelids were constantly affected. Dr. DOWLING asked why in one patient affected with an acute staphylococcal affection of the beard the condition cleared up while another developed sycosis; he thought some constitutional factor must be at work. Dr. J. FERGUSON SMITH (Glasgow) said that the cases associated with blepharitis were really seborrhoeic sycosis. He held that sycosis was essentially seborrhoea *plus* staphylococcic infection. Dr. GARDINER recommended collosol manganese and eusol soap in preventing impetigo from developing into sycosis. Dr. HALLAM expressed agreement with Sir Robert Bolam. The PRESIDENT said that vaccines were useless in his experience. Colonel LONGHURST said that grooms in the Royal Artillery were very frequently affected by sycosis, although discipline compelled them to shave very regularly. Dr. INGRAM replied, and the proceedings of the Section then terminated.

SECTION OF PHYSIOLOGY AND BIOCHEMISTRY.

Friday, July 26th.

PHYSIOLOGY IN THE MEDICAL CURRICULUM.

THE chairman of the third session of this Section was Dr. J. A. MILROY, a Vice-President, who called on Professor F. R. FRASER to open a discussion on the place of human physiology in the training of medical students. Professor Fraser began by comparing the older physiology and the new. Physiology now meant not only the study of individual organs, but also the way in which all the systems reacted to each other and adjusted themselves to changes in the environment. Good adjustment indicated what was called health. In disease an attempt was made to find external factors which had interfered with this co-ordination; hence the importance of physiology to medical men. Textbooks of medicine often gave a wrong impression of the practice of medicine. The necessity of studying the individual differences in patients and their differing reactions was not made clear enough. At the present time, although physiology was taught to every medical student, he did not come to the wards with such knowledge as would be of most use for the practice of medicine. In the pre-clinical years he could not fully appreciate the significance of physiology to his future medical studies. When he had begun his clinical work and had become able to appreciate the importance of physiology most of his clinical teachers were unable to teach him modern physiology. Also, the postponing of applied physiology suggested that there was a separation between physiology pure and applied which really did not exist. There should be no jump between experimental work on animals to observations in man. Professor Fraser pleaded for more co-operation between the physiologist and the clinician in their teaching of students; they would together find the best way of presenting applied physiology. A teacher must, if possible, be an investigator, in order to preserve his keenness in the subject; here also co-operation of the clinician and physiologist would lead to greater advance of knowledge. During the last ten years some progress had been made in this direction. As for methods in promoting this desirable relationship, American methods were quoted, where the physiological department was sometimes placed close to the wards. Another way was to encourage the young clinicians to become demonstrators of physiology. The heads of departments were so burdened with teaching and administration that it was difficult to work together. The freeing of the clinician from outside duties enabled him to keep in touch with physiology, and to infuse physiological principles into his clinical teaching. Dr. C. G. DOUGLAS (Oxford) commented on the difficulty of making the medical student realize the value of physiology. This might be due to the way in which the subject was presented to him. The present progress in practical human physiology had enabled them to study the body both at rest and at exercise, and its adaptation under varying conditions without interfering with its integrity. He advocated attention to human physiology early in his career. Interest and curiosity in his own body, if once aroused, would provide the student with a ground plan into which details might later be fitted. With regard to practical physiology, it must be admitted that apart from histology, there was a lagging behind, as compared with theoretical physiology. The restricting of studies to nerve and muscle did not arouse a student's interest to the slightest degree. These failed to represent the modern progress of knowledge. If all but the most essential were abolished, and experimental human physiology were developed instead, the teaching of the medical student would be more successful. The objective in a practical course was to get him to appreciate the broad fundamentals from his own experience. Human experiment could be used to make him think quantitatively. Dr. Douglas stressed the importance of studying the sense organs, which could only be investigated satisfactorily in man. To keep teaching abreast of the times expense was involved; this must be faced. Human physiology should be studied as soon as the student entered the department, but reference to disease should not be made too early, because the interrelation of the two could not be grasped at this stage. The function of the whole organism must be constantly kept in view. Sir HUMPHRY ROLLESTON (Cambridge) thought that it would perhaps be better to extend the confines of physiology while still maintaining the idea that there was one physiology, in contrast with comparative and human anatomy, rather than to emphasize the distinction between analytical or laboratory physiology on the one hand and human physiology on the other. This might perhaps be thought to be mainly a question of words, but there was the danger that if only those parts and details of physiology known at the time to have a direct bearing on human disease were insisted upon, the teaching of physiology would cease to lead the way to clinical advances, and that a full recognition of the significance of new observations in medicine would be delayed. It was universally recognized that advances in physiology, which at the time might seem to be devoid of any bearing on practical medicine, might subsequently become most valuable. In the speaker's student days the observations of Langley and others on the granules in the secretory cells of glands did not appear to have any practical application. Without in any way impairing the teaching of pure physiology in the pre-clinical years, much could and had been done to adapt the methods of instruction to the needs of future clinicians. Thus the members of a class could experiment on each other in testing the phenomena of the vascular, respiratory, and muscular systems, and of metabolism; the effects of failure in physiological efficiency, such as cyanosis, oedema, paralysis, anaesthesia, and paraesthesia, in patients from the hospital wards could be correlated with the normal; and histology, whether in the physiological or the anatomical department, could be studied in human instead of animal tissues when there were normally differences. By these means not only might the transition from the pre-clinical to the clinical period be made gradual instead of abrupt, and the watertight character of the curriculum mitigated, but an approach to, and even an anticipation of, the effect of similar teaching during the clinical years might be obtained. The problem by whom, when, and how physiological teaching should be given in the clinical years was, as Professor Fraser had shown, difficult to solve satisfactorily. With regard to the teachers most suitable for this task, it should be borne in mind that physiology, especially in its clinical applications, merged into experimental pathology and pharmacology. A young man primarily trained in physiology who intended eventually to take up clinical work, and who in the meantime was attached to a professional medical unit and had one foot in an experimental pathological or pharmacological department, would, from his extended sympathies, be well fitted to give the required physiological teaching in the wards, where he had a recognized position and was at home. Such a teacher should be free from the limitations inseparable from a purely laboratory or a purely clinical

worker. In hospitals without clinical units the difficulty might perhaps best be met by a pathologist of the physiologico-pathological type mentioned above, if such a one was available. It was to be hoped that the demand would create the supply. The instruction should be given when the students were in contact with patients, and perhaps most suitably in the second three months of their clerking, but a second course should be available later, in the third year of the clinical period, when the students were attending the out-patient departments.

Professor Joseph Barcroft (Cambridge) said, in a letter which was read by Sir Humphry Rolleston, that Professor Fraser's main contention was wholly admirable; "the whole body was fitly framed together," and each part depended upon each other part—qualitatively and quantitatively. Their interdependence meant a position of mutual stability, to which the body would return in health if it was displaced by circumstances from that position. In so far as it did not return health was impaired. The failure of the body to return to its stable state was a matter of pathology, but pathology might rightly be held to include also, not only the actual failure and its signs, but also the causes of failure, of which by far the most prominent in recent years had been bacterial or other parasitic infections. The appearance of a toxin in the blood was an alteration in the internal environment of the organism, just as was an increase of hydrogen ion or a rise in temperature. The reactions to that increase in toxin—which reactions enabled the body to return to its normal condition of stability—were on all fours, philosophically, with the reactions to temperature and to acid-aemia. Fifty years ago pathology was dominated by morbid anatomy, then it became dominated by bacteriology, now it should find a place for what Professor Fraser called human physiology, in so far as this, in his sense, really was pathology. There was no sharp line between physiology and pathology, and the medical student should be shown in physiological lectures and practical work the consequences of impairment of physiological function. All the points in Professor Fraser's remarks about the signs and symptoms of cardiac failure were enforced in the regular physiology course in Cambridge, except that the word "digitalis" was probably not used, but the expression "a drug" or "a medicine" substituted. Alternatively, the medical student had much to learn from consideration of evolution and primitive forms of life, and it would be an ill-balanced course which excluded such learning. Professor Fraser would, doubtless, not agree that the physiology of man was fundamentally different from that of the brute creation, except in detail. Probably, being less adaptable to alterations in external environment, man required, and had acquired, a more rigorous control over the constancy of his internal environment, but the difference was trifling. The reasons for using man as the example were: (1) that it is man whom the doctor is going to treat—a reason which would not apply to a veterinary class; and (2) many important experiments demanded intelligence on the part of the person on whom the experiment was performed. For these reasons, and in virtue of the general considerations put forth so forcibly and clearly by Professor Fraser, quite one-half of the practical experimental work in Cambridge was now done on the students themselves: about one-third was on the nerves, heart, and muscles of the frog; and the remaining sixth on general principles governing oedema, etc., which involved no living organism. Professor B. A. McSwiney (Leeds) was disappointed in Professor Fraser's paper because he had left so little of a disputable nature. He thoroughly approved the suggestion of increasing human experiments in the preclinical years. The student was taught to realize the variations among normals. Not enough attention was given to applying these principles to biochemistry. Experiments on the student himself were numerous in this field. The speaker considered that the chief value of these studies was before the student entered the wards, but they should be continued during clinical work. Much depended on the choice of the teacher. There was a need of full-time appointments for experimental medicine. These officers could link up the departments of physiology and clinical medicine. Room could be found in the curriculum for practical physiology if some less necessary studies were cut out.

Dr. F. W. J. A. Lamb (Manchester) suggested that many practical experiments of an easy kind could be performed on the blood, the circulation, and the sense organs. He advocated a second practical course during the time of clinical work, taking such subjects as dyspnoea and cyanosis. These lectures aroused the students' interest. Physiology was a science subject as well as a medical subject. He preferred not to speak of human physiology contrasted with animal physiology, so much as synthetic and analytic. Lectures were a necessity, as also was a good equipment. Dr. J. A. Ryle agreed with Professor Fraser that enough had not been done. He approved of the appointment as medical registrars of men who had worked in the physiology department. He discussed Dr. Batten's views on defining the limits of the normal. As instances of practical physiology he mentioned the examination of the intestinal tract with the barium meal and the sigmoidoscope; also the examination of the circulation and the fundus oculi. Where there was no medical unit these difficulties of teaching applied physiology were greater. He suggested that this teaching should continue right through the medical curriculum. Co-operation of the different departments would be more likely to achieve their object rather than the establishment of a special department. Professor A. V. Hill agreed with the previous speakers as to the importance of practical human physiology. He explained that the nerve muscle work was allotted its proper proportion. He emphasized the great danger of insisting that the head of physiological departments should be medical men. The majority might be, but care must be taken not to exclude from such positions men approaching the subject from other sciences, such as physicists and biologists. This would be very bad for physiology. Another point was that bad experiments on man were not as good as satisfactory animal experiments. Care must be exercised in selecting satisfactory human experiments. Dr. H. W. Davies (Leeds) said he preferred to put these human studies early in the physiology course and continued then in advanced courses after the second M.B. Medical units made the problem much simpler as regards the continuation of these principles. A background of experimental medicine during the study of physiology gained the students' interest and facilitated teaching. He disagreed with the occasional entry of physiologists into wards; it must be regular if it was to be useful, and medical units enabled this to be done. Dr. C. G. Imrie (Sheffield) spoke of Professor Leathes and his early introduction of physiological investigations into the physiology course. He considered that bedside teaching of physiological principles was essential. Professor H. S. Raper (Manchester) was of the opinion that some changes were desirable to increase the students' interest. In biochemical studies the material studied should be obtained direct from biological sources and not from bottles. With present staffs it was not possible for the physiological department to continue the teaching of applied physiology. A special appointment might be made for this purpose. The teaching of pure physiology must not be neglected in a university. He emphasized the importance of self-examination by the student. He was accustomed to using radiological methods in teaching students. Dr. J. A. Milroy (Chairman) wished to see a special department of applied physiology. He spoke of the danger of exceeding the limits of assimilation of the students. Professor Fraser, replying, spoke of his satisfaction in hearing what was being done in the preclinical years. Little mention had been made of the later ward teaching and its difficulties. He agreed with Professor Hill that the professor of physiology should not necessarily have studied clinical medicine, but he wished that the physiologist would sometimes enter the wards in order to help in suggesting investigations and their methods. Dr. Douglas, in his reply, discussed the effects of a lack of human physiology introduced early in the course. He considered that in time there would be a supply of clinical teachers with physiological knowledge.

SECTION OF HISTORY OF MEDICINE.

Friday, July 26th.

THIS Section met under the presidency of Dr. E. M. BROCKBANK, and its business consisted of five papers, the first of which was read by the PRESIDENT, and entitled "John Dalton, physiologist and would-be physician." He chose this subject because he had heard personal accounts of Dalton from relatives, who on their part had hearsay information from their forebears who lived with him. Several unpublished letters were read, giving an account of his desire to take up physic and of his comments on the discouraging criticism of relatives to whom he had communicated his wishes. Eventually he accepted the post of teacher of mathematics and natural philosophy in the Manchester College, and joined the local literary and philosophical society, where he read five papers on physiological subjects. The most important of these was on colour vision, in which he described carefully, for the first time, various forms of colour-blindness, of which he was a subject himself. This defect was called Daltonism for some time. The other papers were on the mind; on the mechanical effects of atmospheric pressure on the animal frame; on respiration and the causes of animal heat; and on the quantity of food taken in health compared with the quantity of the excreta during the same period. Dalton's want of tolerance of other people's opinions until he had tested them for himself, and some rather remarkable conclusions which he drew, were referred to. Some personal characteristics, and an account of his association with doctors and medical studies, concluded the paper.

Sir D'ARCY POWER then read a paper on "Surgeons who were never surgeons," in which he gave short accounts of the lives of those who obtained the Fellowship of the Royal College of Surgeons of England without having practised and sometimes without having intended to practice. He told of Richard Robert Madden, who became a notable author and traveller; of William Guybon Atherstone, who identified the first diamond at what is now Kimberley; of Robert James Stone, who wrote notable textbooks on astronomy, chemistry, physiology, and health; of George Redford, who is best known in connexion with sculpture; of Francis Thomas McDougall, who became Bishop of Labuan and Sarawak—the only English bishop who passed the examinations and was admitted to the Fellowship; and, lastly, of Alfred Smee, who became scientist to the Bank of England, and who perfected a system of printing the cheques and bank-notes. All these gentlemen were honoured in their generations and were the glory of their times, although they were never surgeons, for they left a name behind them that their praises might be reported.

Dr. WILSON PARRY'S paper was entitled "A note on the impetus given by religion to surgery during the third epoch of the Neolithic period." He explained that in order to facilitate the exit of demons from the cranial cavity of man it was the custom in the Stone Age (prior to 2000 B.C.) for the priest doctors to trephine the skulls of the living, using only the stone implements of the period. The site chosen for the operation was always on healthy bone, and there were rarely any signs of injury, fracture, or post-operative bony infection. The lumen was either circular or oval and funnel-shaped, and the edges perfectly smooth. These ritualistic operations were far in advance of the surgery of the period, and, being successfully performed, gradually paved the way for cranial operations for the relief of diseases. Dr. Parry showed a large number of lantern slides illustrating his points, and at the close of his paper answered a number of questions.

Dr. G. FLETCHER (Manchester) gave an account of the life and work of Dr. James Braid (1795–1860) of Manchester, a general practitioner who in his day won something of a European reputation for himself, mainly in connexion with hypnotism, the art of which he learnt in 1841 from a travelling mesmerist. He became interested in the subject, and treated hypnotically, with more or less success, many cases suffering from various kinds of rheumatism and paralysis, as well as cases of deaf-mutism, failing vision, corneal opacities, and tic-douloureux. He was not the first to discover the hypnotic state nor was he the first to assert that this state was wholly subjective; but he did reach that conclusion independently and by dint of much experiment, and he also devised a simple method of producing hypnosis. His great merit lay in the fact that he stripped mesmerism of its occult and baseless extravagances, and reissued it in the form of hypnotism for the service of the physician and the psychologist. To his work is directly attributable the subsequent developments of hypnotism in France and elsewhere, and for this work he ranks with the notable figures in the records of Manchester medicine.

The last paper was read by Dr. E. BOSDIN LEECH (Manchester) who gave an account of the work of Dr. Charles Harrison Blackley, a pioneer in researches into the causation of hay fever by pollen, work which, though recognized in America, is still practically unknown and unrecognized in his own country. He was born in Bolton in 1820, and became a general practitioner in Manchester. Himself a sufferer from hay fever, he recorded in detail the symptoms of his own disease, and used himself for experiments designed to discover the causation of the disease and the best methods for its relief. His claim to fame lies in the fact that, whilst others had described the disease and had theorized on its cause, he experimented and proved that it was due to pollen. As he himself stated, he started out to test by actual experiment the validity of the various opinions on the cause of the disease. He experimented with the air of the town, comparing it with that on the edge of the town and that of the hayfield, and regulating his holidays to sea or country that he might try new areas for his investigations. He tried the effect on himself of all sorts of grasses and flowers, choosing certain fields in turn, according to the crops growing in them, in all experimenting with thirty-five different natural orders, and as a result he brought extensive evidence to show that pollen was the cause of hay fever. In his lifetime Blackley, like many pioneers, was looked upon as somewhat of a faddist—a man who played with grasses—but in reality he is one of whom both Manchester and England may justly be proud.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A SIMPLE METHOD OF REMOVING TONSILS.

BY the following technique we believe that most general practitioners should be able to remove tonsils safely and efficiently. Our opinion is derived from a series of several hundreds of cases which we have treated by this method during the past twelve months.

Anaesthetic.—In children up to about the age of 12 years anaesthesia is inducted with ethyl chloride on an open gauze mask of the type used in ordinary general anaesthesia, followed by ether until the patient is well under, when ether and oxygen are given through a Boyle's apparatus. For older children and adults a chloroform-ether mixture is used for induction.

Method.—The patient is put into position lying on his back, and after induction a sandbag is placed under the shoulders and a Davis-Boyle's gag introduced. The gag gives an excellent exposure of the fauces, maintains the tongue in position, and carries, as an integral part of the tongue-piece, a tube for connecting with the anaesthetic apparatus. The gag may usefully be held by a University College pattern jack. Illumination is provided by a head mirror and a Phelps lamp. The tonsils are gripped at the anatomical upper pole with tensil forceps, preferably not toothed, and the tonsil is pulled as far as possible from its bed. The mucous membrane of the anterior pillar close to the tonsil is then snicked with a pair of special scissors (made by Down Bros.) with long handles and blades curved on the flat, which also act as blunt dissectors, and the space between the capsule and faucial muscles defined. It is of advantage next to separate the upper pole first, and then to enucleate the tonsil by blunt dissection. In doing this the most difficult part is in the region of the lower pole and lingual tonsil, but with care the difficulty can be overcome. It is important to see every stage, and frequent swabbing may be necessary, but when once the tonsil is completely enucleated

bleeding is usually comparatively slight, and can, if necessary, be controlled by crushing the bleeding vessel with artery forceps; or, if there is a general ooze, by firm pressure with a swab for several minutes. The whole operation, except with the most grossly adherent tonsils, occupies about ten minutes. We have only rarely found it necessary to ligature bleeding vessels, and have never had to obliterate the tonsillar fossa by sewing up the anterior and posterior pillars.

After-treatment.—Sponging the face and throat with iced water is useful. Before recovery from the anaesthetic a rectal saline, containing potassium bromide and calcium lactate āā gr. xx, is given, and to this syr. chloral ʒj is added in adult cases.

Dissection seems to us the method of election. We are sure that patients treated by our method will not return with tonsils that have "grown again," as they so often do after the guillotine operation. Securing complete haemostasis before returning the patient to the ward, even at the sacrifice of a little time, seems to us to be desirable.

We have found ethyl chloride given by this open method to be a perfectly safe anaesthetic for young persons. One precaution we take is to discontinue its use if there is not an immediate flushing of the face after the first spray is given.

We are well aware that this technique is practised by others. We would only urge that it be more widely adopted by non-specialists, and feel sure that then tonsillectomy will be more efficiently performed and with less risk.

We are indebted for his help and advice to Dr. R. Ellis, surgeon to this hospital.

Resident Medical Officers, Taunton and Somerset Hospital.

VOLVULUS OF THE CAECUM FOLLOWED BY VOLVULUS OF THE JEJUNUM.

IN the *British Medical Journal* of March 16th (p. 500), I described three cases of volvulus of the sigmoid flexure of the colon successfully operated on in 1928. The case now related was admitted to the Bedford County Hospital on May 6th, 1929. For the notes I am indebted to Mr. J. S. Whiting, house-surgeon of the hospital.

J. P., a labourer, aged 56, had been subject to indigestion. On May 5th, 1929, he had a sudden severe attack of abdominal pain and vomiting. Next day he was admitted to hospital. The abdomen was distended, especially in the upper half, tender, and very rigid. There was no great difficulty in breathing. The diagnosis was probable rupture of a duodenal ulcer.

Operation.—The abdomen was opened through a right upper paramedial incision. An enormously distended large intestine presented, which turned out to be the caecum and ascending colon twisted just below the hepatic flexure. The distended coil had passed upwards and to the left, and lay transversely. An opening was made in the caecum and a tube tied in. The other end of the tube was brought out through a small incision in the usual position of a caecostomy, where the caecum and tube were fixed. The caecum now occupied its normal position. The pelvis was drained through a suprapubic incision, as the peritoneal cavity contained some discoloured fluid. The original incision was then closed.

On the following day the patient was very well and the caecostomy draining freely. On May 8th, about midday, the patient vomited some dark-green fluid, and it was then thought that he had acute dilatation of the stomach. The stomach was washed out repeatedly with a solution of sodium bicarbonate, rectal salines containing brandy were given, also strychnine, pituitrin, and digitaline subcutaneously. On May 9th, at 7 p.m., he died.

Post-mortem Examination.—The stomach, which contained half a pint of green fluid, was much distended with gas. The duodenum and commencement of the jejunum were dilated to about three times their normal calibre. The dilatation was caused by a volvulus of the jejunum, which consisted of a double twist three feet below the duodeno-jejunal junction. The small intestine below this and the large intestine were collapsed. Signs of old peritonitis were present. The caecum was collapsed and healthy. In the ascending colon, six inches from the ileo-caecal valve, was some thickening, which indicated the site of the volvulus. The mesentery of the caecum and ascending colon was considerably longer than usual. The other abdominal viscera showed nothing abnormal.

W. GIFFORD NASH, F.R.C.S.,
Surgeon, Bedford County Hospital.

Reviews.

SLEEP AND ITS DISORDERS.

Sleep and the Treatment of its Disorders,[1] by Dr. R. D. GILLESPIE, is a useful addition to the Minor Monograph Series. It is the aim of the author not only to indicate methods of treatment which might be suitably employed in disturbances of sleep-rhythm, but also to provide, however provisionally, a rational basis for the methods recommended. This aim is admirably realized. In compact form and readable style this book provides the medical practitioner with an outline of the physiology and pathophysiology of sleep: the effects of sleeplessness; the treatment of disorders of sleep; and the various theories of the nature of sleep. The time is certainly ripe for a book of this kind. During the last few years a considerable number of data, experimental and clinical, normal and pathological, having a bearing upon the problem of sleep, have accumulated, and a variety of theories on this subject have been formulated. A work such as this, in which recent observations are outlined, and the latest theories submitted to critical discussion, therefore meets a definite need. In concluding his book Dr. Gillespie states that the body of evidence which has been considered supports the conclusion which R. Dubois reached thirty-three years ago, when, as a result of experimental work on marmosets, he proved to his own satisfaction that there existed in the floor of the third ventricle a "centre for waking" which was one and the same with a "sleep-centre."

THE NOSE, THROAT, AND EAR.

THE long-awaited American system of otology and laryngology[2] edited by CHEVALIER JACKSON and GEORGE M. COATES has now been published. The seventy-five contributors are mostly Americans, but there are several from France, including E. J. Moure and Lemaitre, and from Great Britain including StClair Thomson and Logan Turner. It is confined to a single volume weighing six pounds, but it aims to give practical information on all relevant subjects. The editors say, "What to do and how to do it has been considered the kind of information for which most readers will consult this book." For this reason almost everything historical has been excluded, and there is very little attempt to show how the present practice of otology and laryngology has been evolved in any of its various fields. The editors have no doubt judged their public correctly, perhaps on the dictum of "Cut Hippocrates right out, and begin at the day before yesterday," but this severely practical point of view results in the loss of much that is not only of profound interest but of importance to a proper comprehension of the actual state of knowledge and practice.

It would be scarcely possible to avoid some overlapping when the writing has been distributed among so many authors, and it is only natural that some conflict of opinion should appear occasionally. This in no way detracts from the value of the articles, for when subjects are discussed in such detail many doubtful points must arise. There is, however, a lack of uniformity in the manner in which the various writers have approached their tasks. As instances of sections which seem to be perfectly suited in scope and style to their setting those on the tonsils by Birkett and on the diagnosis of intracranial complications of aural disease by Eagleton are striking, for they are not too long; they are packed with information, and are interesting to read. It would be easy to mention many others of great merit, such as Barnes on neoplasms of the nose and nasal accessory sinuses, Moure on the vocal organ in singing, and Tucker on cicatricial stenosis of the larynx. There are, however, some sections in which the editors have allowed the riders of hobby-horses to mount their steeds and ride them at full speed

[1] *Sleep and the Treatment of its Disorders.* By R. D. Gillespie, M.D., M.R.C.P., D.P.M. London: Baillière, Tindall and Cox. 1929. (Cr. 8vo, pp. ix + 267; 5 figures. 7s. 6d. net.)

[2] *The Nose, Throat, and Ear, and their Diseases.* Edited by Chevalier Jackson, M.D., Sc.D., LL.D., F.A.C.S., and George Morrison Coates, M.D.; assisted by Chevalier L. Jackson, M.D. Philadelphia and London: W. B. Saunders Co. 1929. (Roy. 8vo, pp. xvi + 2177; 657 figures. 60s.)

over the allotted course. It would appear that the editors, having chosen an acknowledged authority on some subject, have given him a certain space and interfered as little as possible. A firmer grasp of the editorial hand might have eliminated in these sections much that is trivial or ephemeral. The section relating to tracheotomy and endoscopy is for the most part from the pen of Chevalier Jackson himself, and is a reflection of the work that is already well known and has earned him a world-wide reputation. There are, however, in this section brilliant articles on the anatomy and anomalies of the œsophagus, on cardiospasm, and on retropharyngeal diverticulum by Mosher.

It would be impossible to appraise the merits of all the articles, so varied and so diverse, but as they must be taken collectively, it may be said that on the whole they maintain a high level and give a faithful picture of the best modern practice, with copious illustrations and admirable coloured plates.

ACTINOTHERAPY.

THE mass production in this country of books on light therapy is paralleled in France, and there, as here, the quality of the product is variable. But two volumes published this year in Paris are of real value, for they carry the weight of considerable practical experience.

The book by Dr. SAIDMAN on the ultra-violet rays in therapeutics[3] is a much extended and improved second edition of a work first published in 1925. In a preface the author adopts the novel expedient of explaining by means of answers to an imaginary questioner the reasons for ultra-violet treatment, its methods, and its place in medicine, and outlines the subject-matter of the book. The physics and physiology of light treatment are admirably set forth, but there is an evident discrepancy between the biological theories underlying actinotherapy and the results of its practice. It is claimed that ultra-violet light has the effect of stimulating the blood-forming organs, but precise experimental information on the point is wanting, and it is quite likely that the improvements in the blood of tuberculous patients under light treatment are explicable rather by their improved general condition than by any direct action of ultra-violet or other radiation. The ultra-violet rays of the sun do not come within the scope of this book, for only those derived from artificial sources are discussed. All kinds of lamps are described, together with hints on their selection according to the object intended. The reader is warned to take the manufacturers' advertisements with reserve, a warning which should apply equally in our own country. The author's polymetallic carbon arc is an attempt to combine the advantages of abundant ultra-violet radiation, such as the mercury vapour lamp provides, with the milder action of the simple carbon arc, whose effects are so largely referable to luminous rays. An automatic clockwork sensitometer for the estimation of the erythema dose is described and figured in some detail. The lengthy bibliographical index contains many misspelt names, even of French authors.

Drs. E. and H. BIANCANI have already written on the ultra-violet rays, and their present volume in the same series has for its territory the visible and infra-red rays,[4] interest in which has been somewhat eclipsed by the invisible rays of short wave-length whose effects are so striking and dramatic. Nearly half the book is devoted to physical and biological considerations, about which the authors have much that is interesting and instructive to impart. They present an adequate study of the phenomena of photosensitization, in the production of which certain drugs may come to have a practical application in light therapy. In discussing the problem of antagonism between rays of different wave-length—especially the empirical fact that previous exposure of the skin to infra-red radiation diminishes its sensitivity to subsequent irradiation with ultra-violet light—the authors suggest that the antagonism is physiological rather than physical, the skin being so altered by the first exposure as to undergo a delayed and less intense erythema from the second. Other matters they deal with in a detailed and competent manner are the choice and handling of apparatus, the selection of defined tracts of the spectrum by filtration, the association of the rays with other physical agents, and the indications for treatment by irradiation. Neither in this book nor in Dr. Saidman's is there a general index, but in both the authors supply a list of diseases in whose treatment actinotherapy is indicated. Both works contain much that is hypothetical, and much also that merits further investigation.

PHARMACOLOGY AND THERAPEUTICS.

PROFESSOR H. A. MCGUIGAN of the University of Illinois, in his *Text-Book of Pharmacology and Therapeutics*,[5] has aimed at providing the medical student with a readable account of the subjects within a reasonable compass. If he has not fulfilled his intention it is largely because, in any presentation of the whole field of pharmacology, brevity can be attained only by setting out much of the material in what is practically a catalogue of facts and dogmatic assertions. A great mass of detail has to be included; and in relation to much of this our knowledge is so fragmentary, and conflicting theories are so many, that only seldom is it possible to give an accurate and yet concise account of the action of a drug.

The book opens with a short dissertation on the principles of physical chemistry. This subject, too, is one which does not lend itself readily to summary treatment, and we doubt if the student unfamiliar with the material would follow easily the description of Donnan's equilibrium, which the author has condensed into half a page. The rest of his subject he has arranged under the heading of the important drugs or groups of drugs. In some cases his principles of arrangement are not quite clear; for example, the chapter headed "lipins or lipoids" contains, as is only right and proper, an account of the fixed oils, fats, and phosphatides. Within it are also included insulin, vitamins, volatile oils, carbohydrates, and glucosides. It is difficult to follow the author's train of thought in this matter; cod-liver oil probably suggested vitamins, and by an easy transition of free associations the name "volatile oil" came to mind, bringing with it the terpines; but how the carbohydrates and glucosides crept in we cannot imagine. Unfortunately, the inclusion of such a diversity of substances under a common heading is likely to suggest to the student relationships that do not exist, and the book would, in our view, be improved if this heterogeneous group were carefully sorted out and its components allocated to their proper places. A similar criticism applies to the author's classification of paratyphoid extract, thymol, and sulphocyanides under the heading "Iodides."

Taken as a whole the book contains a fair and readable account of modern pharmacology and of recent advances in knowledge. It is surprising, however, to find no mention of the therapeutic value of liver extract in pernicious anaemia. Careful examination of the book confirms the author's own statement that he has drawn freely from various standard works on the subject.

SURGICAL ILLUSTRATIONS.

EVERY teacher of surgery realizes the importance of the graphic illustration of the facts which he places before his students. In *A Graphic Guide to Elementary Surgery*[6] Professor NAEGELI has attempted to carry out this idea in detail, and with considerable success. It is true that his illustrations are for the most part thumbnail sketches, and an artist might consider them somewhat crude, but in every single instance the picture shows what it is intended to represent, so much so that it would be quite possible for a student to go through the whole book and get a very fair idea of the elementary principles of surgery

[5] *A Text-Book of Pharmacology and Therapeutics.* By Hugh Alister McGuigan, Ph.D., M.D. Philadelphia and London: W. B. Saunders Company. 1928. (6 × 9¼, pp. 660; 43 figures. 28s. net.)

[6] *A Graphic Guide to Elementary Surgery.* By Professor Dr. Th. Naegeli. Translated by J. Snowman, M.D., M.R.C.P. With an introduction by Dr. C. Garré. London: J. Bale, Sons, and Danielsson, Ltd. 1929. (Roy. 8vo, pp. 205; 322 figures. 12s. 6d. net.)

without ever reading a single word of the letterpress. Only those who have attempted to produce such illustrations can realize their difficulty or how easy it is to lose the *whole point* of the illustration in an effort after artistic perfection. We can *most strongly recommend* Professor Naegeli's *Guide*, both to the student and to his teacher, for there is not a single illustration in the book which could not be produced in a few lines on a blackboard in the course of a lecture. An excellent translation of the letterpress by Dr. SNOWMAN furnishes explanatory comment wherever this is necessary, but it is essentially upon its illustrations that the book depends for its utility and its attractiveness.

GUY'S HOSPITAL REPORTS.

THE third quarterly instalment of *Guy's Hospital Reports*[7] opens with a sympathetic obituary notice of the late Dr. George Newton Pitt by his colleague Dr. John Fawcett, who says, "Whether at Guy's or elsewhere, Pitt exercised his faculties and expended his superabundant energy largely for the benefit of others," and shows that he was the first physician in London to recognize the pioneer work of James Mackenzie, and to apply it in his own teaching. The first of the seven professional articles is Dr. Maurice Campbell's valuable analysis of the hundred cases of auricular fibrillation which occurred among 500 consecutive patients sent to the cardiographic department of the hospital; 53 of the cases were rheumatic, about 36 arterio-sclerotic, and 11 hyperthyroid in origin; a high blood pressure was not a common feature, for in 4 only was it over 200 mm. Dr. R. D. Gillespie contributes an essay on the clinical differentiation of the types of mental depression, illustrated by cases. A number of unusual cases in the medical out-patient department are described by Dr. E. C. Warner, and Drs. L. W. and R. J. Cann give an account of the diphtheria carrier clinic which was established in July, 1926, at Guy's, at the request of the London County Council, for the investigation and treatment of school children carrying diphtheria bacilli. Mr. A. Ralph Thompson follows up his recent papers on horse-shoe kidney and solitary kidney by one on other congenital lesions of the kidneys and ureters. Dr. G. H. Oriel, demonstrator of clinical chemistry, makes a preliminary communication on a substance, of a proteose nature, extracted from the urine of patients with asthma, urticaria, migraine, some infections which in active allergic conditions give positive skin reactions. An elaborate report of the maternity department of the hospital for 1928 is provided by Mr. G. F. Gibberd, the obstetric registrar.

NOTES ON BOOKS.

THE appearance of a second edition of ROGERS'S *Recent Advances in Tropical Medicine*[8] only eighteen months after its original publication speaks for itself. The scope of this volume was discussed in the notice of the first edition appearing in our issue of January 28th, 1928, and little need be added, except to hope that we may see further editions appearing at short intervals, as it is obvious to the reader of to-day that Sir Leonard Rogers means to maintain the title, and each edition is still to include *recent* advances in tropical medicine. Thus, in the new edition, the use of plasmoquine in malaria is dealt with; the recent observations of Baker and Dodds on renal stasis and the mechanism of suppression in black-water fever find a place; the recent work on yellow fever is referred to, and *B. dysenteriae* Sonne is mentioned as a causative agent in dysentery; treatment by bacteriophage is also noticed. There are some additions to the work on sprue, and reference is made to the use of potassium iodide in leprosy. The book remains approximately the same size, some thirty pages only having been added.

We confess to a deep affection for the West of England, and as it is well known that a great number of readers of the *Journal* share this feeling, we have no hesitation in mentioning here two little books that have lately come into our hands for review—one about Somerset[9] and the other about Devon.[10] Both are early numbers of Bell's Pocket Guides to the English Counties; they are written by S. E. WIMBOLT, and copiously illustrated with reproductions from photographs by EDGAR and WINIFRED WARD. Unlike most works of the kind, they represent true collaboration between author and illustrator. The wrappers say that they are "intended for Devon and Somerset folk as well as for the visitor," and, indeed, there can be few West Country people who will fail to appreciate Mr. and Mrs. Ward's charming photographs of familiar places, or learn something of interest from Mr. Wimbolt's descriptive notes. A better collection of views of Devon and Somerset it would be hard to imagine, and the text, if a shade too exuberant here and there, is well informed and judiciously balanced in its general plan. If there is now nothing new to be said about these delightful counties, at any rate the author and his colleagues have succeeded in putting old things in a fresh light, and the result of their labour of love is two well-produced and handy pocket books, "useful, suggestive, and companionable," at a reasonable price.

The pocket pathological anatomy[11] by Professor E. VON GIERKE will be found of service to students who can read German. It consists of concise abstracts such as a student who is skilful in taking notes would make of the lectures he is attending, and it will serve as a substitute for such notes. Professor von Gierke's object in compiling the book, which consists of two thin volumes, is to prevent note-taking during the delivery of lectures, a custom which he considers to be objectionable as distracting attention and destroying the essential features of lectures as a special mode of instruction.

[7] *Guy's Hospital Reports*. Vol. 79 (Vol. 9, Fourth Series), No. 3, July, 1929. Edited by Arthur F. Hurst, M.D. London: The *Lancet* Limited. (6 × 9¼, pp. 253-378; 1 plate, 14 figures. Annual subscription £2 2s.; single numbers 12s. 6d. each.)

[8] *Recent Advances in Tropical Medicine*. By Sir Leonard Rogers, C.I.E., M.D., F.R.C.P., F.R.C.S., F.R.S., etc. Second edition. London: J. and A. Churchill. 1929. (5½ × 8¼, pp. x + 439; 16 figures. 12s. 6d. net.)

[9 10] *Somerset*. By S. E. Wimbolt, M.A. *Devon*. By S. E. Wimbolt, M.A. Bell's Pocket Guides, "English Counties." London: G. Bell and Sons, Ltd. 1929. (6s. *net each volume.*)

[11] *Taschenbuch der Pathologischen Anatomie*. Von Professor Dr. Med. Edgar von Gierke. 1. Allgemeiner Teil. Zehnte Auflage. Leipzig: G. Thieme. 1929. (6½ × 9¼, pp. 143; 68 figures. M.5.)

PREPARATIONS AND APPLIANCES.

EMERGENCY SURFACE SUTURES.

MR. H. DE P. B. VEALE (*honorary surgeon to the Ilkley Coronation Hospital*) writes: I have devised, and Messrs. A. de St. Dalmas and Co., Ltd. (Leicester) have made for me, what may be described as "surface sutures" ("Surfasutes"). They are intended to do away largely with the necessity for using clips or a needle to suture lacerated wounds. The device consists of strips of specially adhesive plaster cut in various shapes and sizes, each furnished with small smooth eyelets. As shown in Fig. 1, after the laceration has been cleaned, sterilized, and

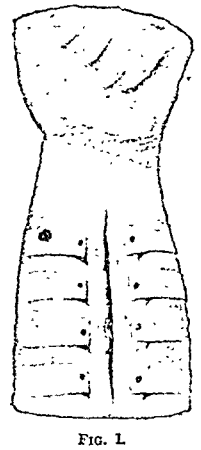

FIG. 1.

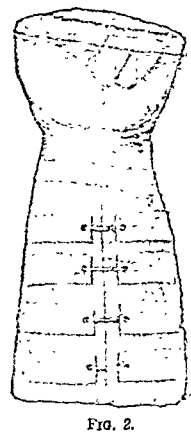

FIG. 2.

dried, they are laid in interrupted position on each side of the wound, the eyelets being about half an inch distant from the cut edge. A sterile curved needle and silk, or silkworm gut, is then passed through the eyelets instead of the skin, and the edges of the wound can be accurately approximated, as shown in Fig. 2.

There are many obvious advantages. The sterile surface sutures, needle, and silk or silkworm gut can be carried in the doctor's bag, and are always ready for immediate use. The pain of stitching is entirely done away with. No stitch scars are left, and there is no danger of stitch abscesses. Dressings can be changed without disturbing the surface sutures. The plaster strips are antiseptic and specially adhesive, and therefore cannot slip. The smooth surface of the eyelets is in contact with the skin, and therefore there is no chafing. The eyelets can be raised for the ready introduction of the sutures, because the adhesive surface does not run beyond them, but is enfolded to strengthen their insertion.

These sutures are obtainable from Mr. Chas. F. Thackray, Park Street, Leeds.

over the allotted course. It would appear that the editors, having chosen an acknowledged authority on some subject, have given him a certain space and interfered as little as possible. A firmer grasp of the editorial hand might have eliminated in these sections much that is trivial or ephemeral. The section relating to tracheotomy and endoscopy is for the most part from the pen of Chevalier Jackson himself, and is a reflection of the work that is already well known and has earned him a world-wide reputation. There are, however, in this section brilliant articles on the anatomy and anomalies of the œsophagus, on cardiospasm, and on retropharyngeal diverticulum by Mosher.

It would be impossible to appraise the merits of all the articles, so varied and so diverse, but as they must be taken collectively, it may be said that on the whole they maintain a high level and give a faithful picture of the best modern practice, with copious illustrations and admirable coloured plates.

ACTINOTHERAPY.

THE mass production in this country of books on light therapy is paralleled in France, and there, as here, the quality of the product is variable. But two volumes published this year in Paris are of real value, for they carry the weight of considerable practical experience.

The book by Dr. SAIDMAN on the ultra-violet rays in therapeutics[3] is a much extended and improved second edition of a work first published in 1925. In a preface the author adopts the novel expedient of explaining by means of answers to an imaginary questioner the reasons for ultra-violet treatment, its methods, and its place in medicine, and outlines the subject-matter of the book. The physics and physiology of light treatment are admirably set forth, but there is an evident discrepancy between the biological theories underlying actinotherapy and the results of its practice. It is claimed that ultra-violet light has the effect of stimulating the blood-forming organs, but precise experimental information on the point is wanting, and it is quite likely that the improvements in the blood of tuberculous patients under light treatment are explicable rather by their improved general condition than by any direct action of ultra-violet or other radiation. The ultra-violet rays of the sun do not come within the scope of this book, for only those derived from artificial sources are discussed. All kinds of lamps are described, together with hints on their selection according to the object intended. The reader is warned to take the manufacturers' advertisements with reserve, a warning which should apply equally in our own country. The author's polymetallic carbon arc is an attempt to combine the advantages of abundant ultra-violet radiation, such as the mercury vapour lamp provides, with the milder action of the simple carbon arc, whose effects are so largely referable to luminous rays. An automatic clockwork sensitometer for the estimation of the erythema dose is described and figured in some detail. The lengthy bibliographical index contains many misspelt names, even of French authors.

Drs. E. and H. BIANCANI have already written on the ultra-violet rays, and their present volume in the same series has for its territory the visible and infra-red rays,[4] interest in which has been somewhat eclipsed by the invisible rays of short wave-length whose effects are so striking and dramatic. Nearly half the book is devoted to physical and biological considerations, about which the authors have much that is interesting and instructive to impart. They present an adequate study of the phenomena of photosensitization, in the production of which certain drugs may come to have a practical application in light therapy. In discussing the problem of antagonism between rays of different wave-length—especially the empirical fact that previous exposure of the skin to infra-red radiation diminishes its sensitivity to subsequent irradiation with ultra-violet light—the authors suggest that the antagonism is physiological rather than physical, the skin being so altered by the first exposure as to undergo a delayed and less intense erythema from the second. Other matters they deal with in a detailed and competent manner are the choice and handling of apparatus, the selection of defined tracts of the spectrum by filtration, the association of the rays with other physical agents, and the indications for treatment by irradiation. Neither in this book nor in Dr. Saidman's is there a general index, but in both the authors supply a list of diseases in whose treatment actinotherapy is indicated. Both works contain much that is hypothetical, and much also that merits further investigation.

British Medical Journal.

SATURDAY, AUGUST 17TH, 1929.

CARDIAC SYPHILIS.

AMONG the subjects of far-reaching importance that periodically come up for discussion at the Sectional Meetings of the British Medical Association the two great infections syphilis and tuberculosis are naturally in the first rank. At the Newcastle Meeting in 1921 the late Sir Clifford Allbutt opened a discussion in the Section of Medicine on visceral syphilis, especially of the central nervous and the cardio-vascular systems, and at one point in his comprehensive review remarked, "of congenital syphilitic disease of the heart we may guess much but we do not know much." This, though not perhaps of outstanding importance, is worth recalling as its hint has now been taken and the condition elucidated. At the Manchester Meeting last month Professor Alfred Scott Warthin, of the University of Michigan, Ann Arbor, spoke both in the Section of Venereal Diseases (*Journal*, August 10th, p. 236) and in the course of the discussion on syphilis of the heart and aorta, opened by Drs. John M. Cowan and J. Steven Faulds, in the Section of Medicine, where he gave a beautiful and convincing lantern slide demonstration on the cardio-vascular lesions of latent syphilis. Great interest must attach to his observation (and his experience is very extensive) that he has never seen at necropsy a case of cured syphilis; search, often be it noted prolonged, has always revealed active latent lesions in the aorta, heart, or other organs; further, he contested the validity of the argument that the now numerous reported cases of a second attack of syphilis prove that a previous syphilitic infection had been cured. Remarkable microscope slides were shown of the lesions—cell infiltration, oedema, myxomatous change (formerly described as "myxomas"), and spirochaetes—in the heart in congenital syphilis. Professor Warthin also brought out the striking difference in the two sexes of the localization of the latent syphilitic lesions; this was so well marked as to suggest a radical distinction of the male and female constitutions: in males with latent syphilis the heart and aorta are invariably affected, whereas among syphilitic females the cardiac lesions are absent or, if present, slight, and the aorta, though usually involved, is so in a much less degree than in males. The great majority of his cases of latent syphilis came under clinical observation with a definite clinical picture—some degree of myocardial failure with dyspnoea, cyanosis, and chronic venous engorgement—and were commonly but erroneously labelled as "rheumatic," especially in the young. Death from latent syphilis was most often due to cardiac insufficiency, and a large proportion of the deaths in middle life from myocardial degeneration were caused by latent syphilis; four years ago he reported a series of sudden deaths, all in men, of this nature. As he considered that in young patients latent syphilis of the heart probably disposes to secondary bacterial endocarditis, the questions might be asked, Does not rheumatic infection also supervene? and May not both factors play their parts in bringing about cardiac failure?

It may be interesting to compare these pathological data and deductions with current clinical opinion. The reasons for divergence between the bedside and the laboratory diagnoses are fairly obvious; the clinician peers through a glass darkly, whereas the pathologist has before his eyes evidence invisible during life. In these circumstances the physician has no doubt often paid too much respect to a negative Wassermann reaction, and in the absence of all signs and symptoms of syphilis has regarded a negative serological test as confirming the exclusion of a luetic origin for the cardiac disability. This opens up difficult problems; what of course is urgently needed is some clinical criterion which indicates a syphilitic form of cardiac failure, in the absence of any gross or serological evidence of syphilitic infection. Drs. Cowan and Faulds, as would be anticipated from Cowan and Rennie's contribution on syphilis of the heart to the discussion at Newcastle in 1921, fully recognize the frequency and importance on the one hand and the diagnostic difficulties on the other hand of syphilitic myocardial lesions. In this connexion it is well to recall Cowan and Rennie's aphorism, "Syphilis has no originality. It is merely a servile copyist"; for it follows that any form of clinical heart disease may thus be produced. The importance of syphilis in the etiology of aneurysm, aortic regurgitation, and angina pectoris is now generally accepted, and the same conception is gaining ground as regards myocardial failure. It is, however, rather surprising how rarely auricular fibrillation is due to syphilitic myocarditis; this was insisted upon by Dr. Crighton Bramwell; and in the current number of the *Guy's Hospital Reports* is an analysis by Dr. Maurice Campbell of 100 cases of auricular fibrillation among which only two were found to be syphilitic. Drs. Cowan and Faulds have evidently searched for some clinical characters whereby syphilitic can be distinguished from other forms of heart disease, and have gone so far as to state that, although the symptoms of rheumatic and syphilitic disease are essentially similar, there are some features peculiar to each, and that the occurrence of symptoms of myocardial weakness without obvious cause should at once suggest the possibility of a syphilitic origin, particularly if the patient is under 60 years of age; thus agreeing specially with the general dictum of Vigo in 1785, quoted in East and Bain's *Recent Advances in Cardiology*, "When you meet with a disease that does not respond to the ordinary remedies, you may think that this is the disease called French."

While the importance of an accurate diagnosis as an essential preliminary to rational treatment is incontrovertible, there is room for discussion whether or not vigorous and prolonged antisyphilitic treatment is the best routine form of treatment for well-marked cardiac failure in a syphilitic patient. In some cases the syphilitic change, though extensive, may be old and stationary, in others it may be progressive, and it may be difficult in a given case to decide this question. In the discussion in the Section of Medicine at Manchester Dr. Boyd Campbell insisted on the value of prolonged and repeated courses of antiluetic treatment, and quoted cases in support of this procedure; while Dr. John Hay held a brief for treatment directed to the cardiac failure. There can, however, be no doubt that the best treatment is on preventive lines—namely, thorough antisyphilitic treatment as early as possible in the course of the infection so as to destroy the spirochaetes before they have become firmly entrenched in the myocardium. As will be seen from their paper, published this week at page 285, Drs. Cowan and Faulds enforce this in the dictum that "cardiac syphilis is the result of error, on the part of the patient or his medical adviser."

ANTE-NATAL CLINICS.

THE failure to effect any reduction in the maternal mortality rate in the ten years following the passing of the Maternity and Child Welfare Act, with the consequent general establishment of ante-natal clinics by local authorities, has naturally given rise to disappointment and to heart-searching for the reasons thereof. As a result of its consideration of this question, the Committee on Maternal Mortality at present sitting at the Ministry of Health has drawn up a memorandum which has been issued by the Ministry as an official document[1] for the guidance of local authorities and their officers concerned, but there is much in it applicable to prematernity work in family practice, and a study of it will repay all who practise midwifery. The British Medical Association has recently expressed very emphatically the opinion that, apart from their educational work, there is nothing essential done at ante-natal clinics that should not be done equally well either at the woman's own house or at the doctor's consulting room. It is admitted that at present a large number of midwives are not fully competent for this purpose and that there are doctors who do not show willingness to undertake the work. Both these unfortunate conditions are, however, in process of being overcome, and, unless general practitioners are prepared to see midwifery go the way of infectious fevers, venereal disease, and tuberculosis, it is essential that they should keep themselves informed of what is expected of public ante-natal clinics, so that they may themselves give like service.

A brief review of its contents may serve to draw attention to this memorandum on ante-natal clinics, published by H.M. Stationery Office at the modest price of one penny. It begins by laying down six principles on which ante-natal care should be based, and these are, shortly: (1) the prevention of foreseeable difficulties in labour; (2) the early detection and treatment of toxaemia; (3) measures for increasing resistance to infection and for the detection and treatment of septic foci; (4) the diagnosis and treatment of venereal disease; (5) co-operation between those responsible for the care of the child-bearing woman; and (6) educational efforts. On these fundamental points there will be general agreement, though regret may be felt at the absence of emphasis on attention to the health of body and mind in the expectant mother. Apart from picking out serious conditions—for example, cardiac, renal, tuberculous—that may be aggravated by pregnancy, a very material part of ante-natal care is the relief of many minor ailments—such, for instance, as digestive disorders, piles, and varicose veins—which by reason of their frequency form a large factor in the disabilities arising out of child-bearing. Nothing serves better to suggest to the women the advantages of prematernity care than that their little troubles and discomforts should have attention, whether in the direction of treatment or reassurance.

Before discussing the application of the principles as laid down, the organization and staffing of ante-natal clinics is considered, evidently in order to forestall what has been the chief criticism made against them—that of putting prematernity work into a separate pigeon-hole and divorcing it from the rest of midwifery practice, and the staffing of clinics by whole-time, and often junior, officers not in obstetric practice and with little or no obstetric experience. These criticisms are not mentioned, nor, so far as we can see, is any real effort made to meet them, except for some praiseworthy suggestions as to co-operation between clinic officers, doctors, midwives, and hospitals. Ante-natal care is successful chiefly where those responsible for it are responsible for the rest of the maternity work, natal and post-natal, and it is in institutions and in private practices where there is continued observation of and responsibility for the woman throughout child-bearing that good results are apparent. Recommendation is made that officers in charge of clinics, whole-time or part-time, should have had post-graduate obstetric experience, preferably in resident posts at a maternity hospital. Valuable as this advice is, the essential condition for successful ante-natal care is not met. The suggestions on co-operation are welcome, for there is no direction in which public health officers can be more helpful than in the staff work of co-ordinating the various units in a maternity service.

The minimum scope of ante-natal examinations, including their extent and frequency, is set out in the final section, and this will appeal more particularly to the general practitioner. One point that a study of the memorandum should make clear is that the doctor ought to have a midwife as his maternity nurse, using her services at his ante-natal examinations, to maintain touch with his patients, advise them on minor matters, and generally play the part for him that the health visitor does in the public clinic. Where this arrangement subsists the doctor delegates to his nurse-midwife the following up and observation of his patients, and the giving of advice as to preparation for the confinement, and he receives and checks her reports at intervals. Without a well-trained woman of this kind beside him he cannot give all that the ante-natal clinics give, for it is on the educational and social side that they have had most success. It is to be hoped that the final words of the memorandum will receive due attention from local authorities and their officers: "Generally speaking, treatment of abnormal conditions is not the work of an ante-natal clinic. Any cases requiring treatment should be referred, whenever possible, to the family doctor, or to a consulting clinic or a hospital. The importance of co-operation between the clinic and the professional attendant cannot be overestimated."

IDENTIFICATION OF FIREARMS USED BY CRIMINALS.

UNTIL recently it has not been considered possible to identify with any degree of certainty the firearm used in connexion with crime, even although the bullet which caused the death and the used cartridge case were available. Authorities admitted the possibility of recognizing certain resemblances, but dismissed the idea of any certain method of identification. There were, of course, experts who were prepared to give an opinion on such matters; but such opinions were, as a rule, *obiter dicta* unsupported by demonstrable evidence of identity. Of late years, however, the investigation of these cases by scientifically minded people has opened up a new field of research, and at the present time the identification of the weapon used in a crime may be made with precision in the greater proportion of cases.

Every bullet fired from a weapon has imprinted on its surface a series of marks. The most prominent of these are the grooves caused by the rifling of the barrel of the weapon used, and these, from their number, direction, width, and pitch, give a fair indication of the type of weapon used. In addition, however,

there are usually individual differences not only in the grooves, but on the surface between the grooves, which are specific to the particular weapon used, and are repeated on any projectile fired from the said weapon. By means of enlarged photographs or by a comparison microscope, which brings the images of the two objects (in this instance the bullet found in the case and another fired from a suspected weapon) side by side in one field, these individual characteristics can be recognized and demonstrated with precision. If a cartridge case has been discovered at the scene of the crime a similar technique is observed, and marks caused by the magazine, firing chamber, breech block, or firing pin may be compared with similar marks on a sample fired from a suspected weapon and definite individual characteristics again recognized. The methods adopted are excellently summarized in a recent paper by Mr. Robert Churchill (*Police Journal*, July, 1929), who took part in the identification of the weapons found in connexion with the murder of P.C. Gutteridge, which caused such a sensation in this country last year. Our readers will also remember the article contributed by Professor Sydney Smith to the *British Medical Journal* of January 2nd, 1926, in which similar methods were described which resulted in the conviction of the murderers of the Governor-General of the Sudan in the previous year.

Medical men play a not unimportant part in all such cases, for in the primary examination of the murdered person information of the greatest value may be obtained or lost according to the knowledge of the practitioner. For example, the marks on the victim's clothing and on the skin may show not only the distance and direction from which the shot was fired, but, if the traces are retained for microscopic and chemical examination, may give a clear indication of the nature of the powder used. Spectroscopic examination of such traces for emission spectra may give valuable evidence, and as such traces are often minute they stand considerable risk of being overlooked, washed off, or destroyed.

Not only in cases of firearm wounds, but in all cases of injury to the person, the medical evidence may be of paramount importance in fixing the guilt or innocence of an accused person, and it would appear that the time has arrived to consider whether sufficient attention is paid to the training of practitioners in forensic medicine in this country. Expert evidence is being used to a greater extent every year in our courts, and the judicial authorities naturally are demanding a higher standard of professional knowledge from medical experts. Our universities and medical schools ought to insist that their graduates should acquire a sufficient knowledge of forensic medicine, so that if called upon to help the investigating authority they are not destitute of the requisite knowledge.

MORPHOLOGICAL VARIATIONS IN BACTERIA.

BACTERIOLOGY has developed very largely as an applied science, for it has been in the investigation of disease that the greater part of our knowledge of bacteria has been acquired. Admittedly this has had its advantages. The stimulus so given to bacteriological research has been immense, and rapid strides in knowledge have been made in consequence. On the other hand, bacteriology as a pure science has suffered, for, though we have learned much about the etiology of disease and the isolation and identification of bacteria, we know next to nothing of their natural history. For long now the monomorphist tradition has dominated our views on the reproduction of bacteria. In recent years, however, the monomorphist conception has been called in question by the work of Lohnis, Hort, Mellon, and others, but the polymorphist view put forward by them has not gained general credence because their evidence has been scanty and unsatisfactory. Professor Arthur Henrici of the University of Minnesota has endeavoured to find out whether bacteria really do pass through some developmental cycle as the polymorphist school claims, and the fruits of his investigations are embodied in a monograph entitled *Morphologic Variation and the Rate of Growth of Bacteria*.[1] This investigation has entailed an immense amount of laborious work, including the measuring and counting of large numbers of bacteria and the observation of changes in form and structure. Professor Henrici admits that he has not gone far enough yet to allow him to dogmatize on the subject, nevertheless his findings warrant the drawing of certain conclusions. Bacteria do appear to pass through a developmental cycle comprising changes in length, affinity for basic aniline dyes, and the development of metachromatic (volutin) granules, each of these changes being quite definitely and constantly associated with a particular growth phase of a bacterial culture. His conception goes further than that of the orthodox monomorphist, but, on the other hand, he fails to find any support for the polymorphist idea of sexual reproduction on the part of bacteria. He certainly noted the appearance of abnormal forms in his cultures, but these invariably appeared when the cultures were dying and the bacteria were undergoing dissolution. Further, these departures from the normal morphology comprised the most varied and bizarre forms, suggesting irregular or patchy autolysis of the bacterial envelope, with consequent cellular asymmetry. These are the forms which the polymorphists have light-heartedly identified as buds, conidia, sporangia, and the like; there seems no good reason for abandoning the orthodox view of their being involution forms. Bacteriologists owe a debt to those who, like Professor Henrici, are endeavouring by their labours to remedy the defect in the foundations of this science which have resulted from too great haste to erect the superstructure.

EXPERIMENTS ON ANIMALS.

THE summer number of *The Fight Against Disease*, the quarterly journal of the Research Defence Society, contains an account of the annual general meeting of the society on June 12th, when Professor A. V. Hill, F.R.S., delivered the third of the Stephen Paget memorial lectures, entitled "Enemies of knowledge." Those who saw the report of this lecture in our issue of June 22nd now have an opportunity to read the full text. They will note that, while denouncing calumnies, Professor Hill pleads for tolerance and fairness in dealing with all arguments on either side which have any rational basis. Elsewhere in the issue appear notes on antivivisection meetings and a protest against the unfounded allegation that the Research Defence Society had anything whatever to do with the deplorable rowdiness at a recent meeting in Caxton Hall. We are glad to learn that Dr. Hadwen himself has not suggested that the society was responsible for what happened on that occasion. The society, now in its twenty-first year, needs further support. The annual subscription is 10s., and life membership costs five guineas; inquiries should be addressed to the honorary secretary, 11, Chandos Street, Cavendish Square, W.1. Opportunely enough, the current number of its journal appears almost at the same moment as the Home Office return for 1928 on experiments on living animals,[2] a sober document well worth studying.

[2] Home Office Return on Experiments on Living Animals. H.M. Stationery Office. 1929. (pp. 70. 1s. 3d. net.)

The report of the chief inspector includes the names of all persons in Great Britain who held licences during any part of the year, together with a statement of the special certificates which were in force, and a list of the 256 registered places at which the licences were valid. The experiments are classified numerically according to their nature. Of the 1,310 persons who held licences, 339 performed no experiments during the year. The table showing the number of experiments returned by each licensee is divided into two parts in order to distinguish experiments performed without anaesthetics from those in which anaesthetics were used. The 14,976 experiments under anaesthesia comprise all those in which any serious operation was involved. The remainder of the experiments on living animals carried out during the year, numbering 300,915, were devoted entirely to inoculations, hypodermic injections, and some few other proceedings performed without anaesthetics. In no case was a certificate dispensing entirely with the use of anaesthetics allowed for an operative proceeding more severe than a subcutaneous venesection. Serious operations are always required to be performed under anaesthesia. Experiments performed without anaesthetics are mostly inoculations, but some are feeding experiments, or the administration of various substances by the mouth or by inhalation, or by external application, or the abstraction of blood by puncture, or simple venesection. "The operative procedures in the experiments performed under Certificate A without anaesthetics are only such as are attended by no considerable, if appreciable, pain." In a very large number of such experiments the results are negative and the animals suffer no inconvenience whatever from the inoculation. Antivivisectionists make great play with the total number of experiments performed without anaesthetics, ignoring the fact that for the most part these are entirely painless procedures carried out on behalf of official bodies with a view to the preservation of public health, or directly for the diagnosis and treatment of disease, or for the testing and standardizing of antitoxic serums, vaccines, and drugs. During the year the several registered places were visited frequently by the inspectors and a large number of experiments were witnessed; for the most part such visits were made without previous notice. The animals were found to be suitably lodged and well cared for, and the licensees generally attentive to the requirements of the Act and the conditions attached to their licences by the Secretary of State. Three irregularities only were reported during the year.

ANOTHER X-RAY DANGER.

An article by Dr. N. S. Finzi in the July issue of *The British Journal of Radiology* calls attention to the risk of x-ray emission from the hot cathode valve tubes used to rectify the high tension current supplied for radiological investigations. These valve tubes are usually sufficiently near to the patient and to the operator for such stray radiation to produce recognizable effects. Dr. Finzi illustrates his warning by reproducing a skiagram of the chest, which clearly indicates irregular shadows cast by x rays which came from his four valve tubes, although these were situated considerably further away from the film than the x-ray tube. Valve tubes are usually mounted inside a wooden cabinet with the transformer and other parts of the generating set, and the walls of such a cabinet, while concealing the apparatus from view, would offer little obstruction to the passage of x rays. It is usual for such tubes to be marked with figures indicating the correct current to be used when operating the set, and if less current is employed than that stipulated then x rays are liable to be produced in such a tube. Dr. Finzi alludes to this in a remark to the effect that the difficulty may be overcome by passing extra current through the offending tube. No doubt the ideal arrangement is that adopted in some large x-ray departments, such as that at Edinburgh, in which the generating apparatus is housed in a separate room, all the walls, ceilings, and floors of the building being constructed of x-ray-proof materials. If this cannot be done, a valve set may be rendered safe from this risk by screening it off from the patient and operator, as by the cabinet being lined with some protective material such as lead-rubber.

RADIUM TRUST AND COMMISSION.

At a meeting of the National Radium Trust held on August 15th under the chairmanship of Lord Parmoor at the Privy Council Office, Viscount Lee of Fareham was appointed chairman of the Radium Commission and to be a member of the Trust, and preliminary arrangements were made in connexion with the purchase of radium, with a view to placing it as soon as practicable at the disposal of the Commission. The National Radium Trust is constituted as follows:

The Right Hon. Lord PARMOOR, K.C.V.O., K.G., Lord President of the Council (Chairman).
The Right Hon. ARTHUR GREENWOOD, M.P., Minister of Health.
The Right Hon. W. ADAMSON, M.P., Secretary of State for Scotland.
Sir ERNEST RUTHERFORD, O.M., President of the Royal Society.
Sir JOHN ROSE BRADFORD, K.C.M.G., M.D., F.R.S., President of the Royal College of Physicians of London.
The Right Hon. Lord MOYNIHAN OF LEEDS, K.C.M.G., C.B., President of the Royal College of Surgeons of England.
The Right Hon. Lord DAWSON OF PENN, G.C.V.O., K.C.B., K.C.M.G., M.D., F.R.C.P., President of the Royal Society of Medicine.
The Hon. Lord MACKENZIE, LL.D., Chairman of the Central Liaison Committee for Voluntary Hospitals in Scotland.
Professor A. H. BURGESS, M.B., M.Sc., F.R.C.S., President of the British Medical Association.
The Right Hon. Viscount LEE OF FAREHAM, P.C., G.C.B., G.C.S.I., G.B.E.

The Radium Commission has now been set up in accordance with the provisions of the Royal Charter, and is composed as follows:

Viscount LEE OF FAREHAM. Appointed by the National Radium Trust (Chairman).
Lieut.-Colonel A. B. SMALLMAN, C.B.E., D.S.O., M.D., Medical Officer of the Ministry of Health. Appointed by the Minister of Health.
H. L. F. FRASER, LL.B., Assistant Secretary, Department of Health for Scotland. Appointed by the Secretary of State for Scotland.
SIDNEY RUSS, D.Sc., Professor of Physics, Middlesex Hospital Medical School. Appointed by the Medical Research Council.
G. W. C. KAYE, O.B.E., D.Sc., Superintendent of the Physics Department of the National Physical Laboratory. Appointed by the Department of Scientific and Industrial Research.

Six members appointed by the Trust from the panel of twelve persons selected by the heads of the medical profession under Article 4 (2) of the Charter, as "having special knowledge and experience of the application of radium in the treatment of the sick":

J. M. WOODBURN MORISON, M.D.Glas., F.R.C.P.Ed., Lecturer in Radiology, University of Edinburgh.
G. E. GASK, C.M.G., D.S.O., F.R.C.S., Professor of Surgery, University of London.
W. ERNEST MILES, F.R.C.S., Surgeon to the Cancer Hospital, Brompton.
COMYNS BERKELEY, M.D., M.Ch., F.R.C.P., F.R.C.S., Gynaecological Surgeon to the Middlesex Hospital.
CARLTON OLDFIELD, M.D., F.R.C.P., F.R.C.S., Professor of Gynaecology, University of Leeds.
ARTHUR J. HALL, M.D., F.R.C.P., Professor of Medicine, University of Sheffield.

PROBLEMS OF THE UNFIT.

There is a good deal of undoubted truth, together with some statements of a more dogmatic character than can perhaps be justified and a few which will not bear strict examination, in an article entitled "The multiplication of the less fit," by Dr. K. B. Aikman, in the current number of the *Edinburgh Review*. The importance of the subject and the urgent need of action in regard to it justify reiterated attempts to keep it in the public mind, but panic propaganda and panic legislation or administrative action are almost always unwise, and are likely to fail in their real objects. There is just a suspicion of such panic in many recent letters and articles in the lay press dealing with the prevalence of mental and physical deficiency and with the question of eugenic reform; and in Dr. Aikman's article the picture is probably a little out of true perspective. The comparative and the superlative are not always kept in their proper places. Referring to the differential birth rate in the various grades of society, Dr. Aikman, following a not uncommon line, says: "A much higher proportion of the middle classes is now on the road to extinction. Some might argue that this would be no great loss, as their places would be filled with the pick of the lower grades of society. . . . Every unprejudiced person will admit that the average level of ability in the great middle class is higher than in the lowest classes." Here a *non sequitur* is patent, owing to a confusion between the "lower" and the "lowest." This confusion pervades, indeed, a good deal of recent argument. There is no biological or practical reason to believe that there is any fundamental difference in stock value at birth between the offspring of the skilled artisans, the bulk of the decent labourers, agricultural or other, and of those commonly regarded as above them in the social scale. History and science alike support this view. It is with the "lowest," not with what some are pleased to call the "lower," that danger lies. Within this lowest class—perhaps almost one-tenth of the whole population—will be found a larger proportion of physically and mentally defective persons than among the rest, but certifiable defectives by no means constitute the whole of this class, nor even the greater part of it. Conversely, physically and mentally defective children are born in considerable numbers in every grade of society; and, though mentally defective parents will tend to produce mentally defective offspring, yet the vast majority of such offspring are not the children of parents who are certifiably mentally defective or insane. Moreover, it has now come to be recognized that a large proportion of those who are intellectually defective are not at the same time socially defective, and that with very slight supervision these can be trusted to behave as decently in the community as the average member thereof, though their economic value be less than the average. It follows from these considerations, first, that the need for provision for segregation of defectives, though more is required than at present exists, is not so immense as is often assumed; and secondly, that the sterilization of certified mental defectives, though probably of value in dealing with particular individuals or families, would be futile as a general preventive measure. Fortunately, this lowest class of society, however constituted, tends to segregate itself, and though its rate of reproduction is above the normal its expectation of life is less than the normal. Dr. Aikman is in error when he says that "everything making for increased expectation of life favours the poorest." Nevertheless, the question of how to deal with the lowest class, with all its difficult interrelated problems, remains and becomes more urgent year by year. It is certain that these problems cannot be solved by any simple legislative enactment. Inquiry, however, as to the way in which the questions of poverty and of deficiency are related to one another, and as to the exact genetic causes of deficiency, is imperatively needed, and, quite apart from inquiry and action by the State, Dr. Aikman is surely right in his suggestion that something at least might be done by impressing upon the fitter citizens the recognition of their duty to have a reasonable number of children, and by insistently pointing out to the younger generation the undesirable consequences to themselves and to their offspring of choosing a mate from a bad stock.

FARADAY CENTENARY, 1931.

The arrangements initiated by the Royal Institution for the celebration of the centenary of Faraday's discovery of electro-magnetic induction are already well in hand. At the meeting held on February 5th last the formation of two committees was agreed to, and these committees are now at work. The first, consisting of representatives of the Royal Society, the British Association, and other scientific societies, as well as the Royal Institution, is concerned with the purely scientific aspects of Faraday's work; the second committee, called together by the Institution of Electrical Engineers, includes representatives of the principal organizations of those industries which have risen in the past hundred years upon the scientific foundation of Faraday's discoveries, and is dealing with the industrial aspects of the celebrations. The two committees are working in close co-operation, and their preliminary discussions indicate that the significance of the centenary is very widely appreciated and that the celebrations are likely to arouse world-wide interest. The proceedings will open in London on Monday, September 21st, 1931, two days before the British Association begins its centenary meeting in London.

MEDICAL RESEARCH COUNCIL.

By an Order of the Committee of Privy Council, Viscount D'Abernon and Mr. A. G. Church, M.P., are appointed members of the Medical Research Council on the retirement of the Earl of Balfour and of Sir Charles Trevelyan, Bt., M.P. Lord D'Abernon will succeed Lord Balfour as chairman of the council. By another Order, made after consultation with the Medical Research Council and with the president of the Royal Society, Professor J. J. R. Macleod, M.D., regius professor of physiology in the University of Aberdeen, and Mr. Wilfred Trotter, F.R.C.S., honorary surgeon to H.M. the King and surgeon to University College Hospital, London, are appointed members of the council in succession to Professor E. P. Cathcart and Sir Charles Sherrington, who retire in rotation on September 30th.

We regret to announce the death in London, in his eighty-second year, of Dr. William Ewart, consulting physician to St. George's Hospital and the Belgrave Hospital for Children. We hope to publish a memoir in our next issue.

The Hungarian Government is offering a prize of 2,000 Swiss francs for an independent essay on the etiology of trachoma indicating definite research. These essays must be addressed to the Eye Clinic No. 1 of the Royal Hungarian Peter Pázmány University, Mária-utca 39, Budapest VIII, not later than June 30th, 1931. Works that have already appeared in print are likewise eligible for this competition. The jury of award may also consider works not submitted for competition but appearing in print between July 1st, 1929, and June 30th, 1931. The essays may be written in German, English, French, Italian, or Hungarian. The jury of award will be appointed by the Hungarian Minister of Public Welfare and Labour, and its decision will be announced not later than December 31st, 1931.

Nova et Vetera.

A SEVENTEENTH CENTURY MANUSCRIPT PRESCRIPTION BOOK.

Before us lies a quaint little book with a request from the owner for information about it. It is a 12mo, 5.25 x 3.1 x 1.3 inches, bound in calf, with the original leather ties. The leather is stout, and the piece not being large enough, the binder has sewn strips on the top and bottom infoldings so that the pasteboards should be adequately covered. The ties, which are of untanned leather with broad ends pasted down on the boards, are quite sound and fasten easily. On the liner of the upper cover is written "Thomas Boraston his Booke." The writing is that of the later of the two main handwritings with which the book is filled. None of the usual books of reference give any account of this name, but there was an ecclesiastical family in Worcester and Herts with several Thomas Borastons in their list, the earliest of whom subscribed at Oxford in 1635.*

The book is essentially a manuscript pharmacopoeia of mid-seventeenth century writing; probably one of those written for medical students by scribes who copied the lectures and extracted from books hand-lists of notes. The custom lasted down as late as the first twenty years of the last century, especially at the great schools in London. This manuscript is unusually full. It gives pharmaceutical directions as to the various medicaments, their kinds, methods of exhibition, such as how to dilute a concentrated preparation to an 8 oz. measure, and so forth. Then there are schemata under the headings of heart, lungs, abdomen, and the other parts of the body, with signs and treatment. The whole of the original work is written in contracted Latin and in a hand of the first half of the seventeenth century; very neat and easily read, with the headings and the chief words of the paragraphs written in red ink.

The first leaf is filled with an account of the conditions following conception. It is written in a somewhat later hand, and the writer has added here and there throughout the book notes and prescriptions enlarging those of the original script; some of these are in English. The extract is as follows:

"The sign of Conception for ye woman. The first day after Conception she feels a slight quivering rushing al through the whole body a tickling in ye womb & a little paine in ye lower pts of ye belly 10 or 12 days after ye hede is affected with giddiness ye eyes with dimness of sight, then followes red pimples in ye face with a blew circle about ye eyes ye breasts swell & grow hard wth some paine & pricking in the', ye belly suddenly sinketh and riseth againe by degrees w'th a hardness about ye navill ye nipples of ye brests waxe red ye hearte beats inordinately ye appetite dejected yett she hath a longing desire after straingo meats, ye necke of ye wombe is retracted yt it can hardly be felt by ye finger being putt up & this is an infallible signe. She is soone merry & soone sad her monthly courses are stayde wthout any evident cause, her excrements likewise unaccustomably retained by ye wombe pressing ye great gutt & her desire to vent is abated. The surest sign is taken from ye infant wh begins to move in ye 3d or 4th month & yt not in manner of a mole fro' [ye] side like a stone but mildly as may be p'sed [perceived] by applying ye hand hott on ye belly. The urine is white & hath little nodes [? motes] like those in ye sun & a cloud swi'ming, ye last of an opall coloure ye sediment being divided by shaking of ye reines .... appeares like carded wool. In ye middle of her time ye urine turneth yellow, next red & lastly blacke wth a red cloud. Ergo from experience atte night going to bed lett her drinke water & hony afterwards if shee feeles a heating paine in her belly & about her navill she hath conceived or else take the juice of cardu' [carduus benedictus] and if she vomit it uppe it is a signe of Conception. Cast a cleane needle into a womans urine put into a brazen bason lett it stand all night & in ye morning if itt be coloured with redd spotts she hath conceived, butt if it be black or rusty she hath nott. Beinge with child of a male ye right breast swells first ye right eye is more lively than ye left her face well coloured & red motes in ye urine settling downe to ye sediment, butt if white [motes] a female. Putt a womans water who is with child into a glasse bottle let it stand close stopt 3 days then straine it through a fine cloath & you shall find little living creatures, if red a male, if white a female."

There are prescriptions given, too, to aid conception. This extract practically dates the book; it is the sort of thing found in *The Women's Book*, Culpeper, and a whole host of writers down to the time when Harvey began to rationalize treatment and theory. It lingered on into the eighteenth century, and some of it still appears in the so-called *Secrets of Aristotle*, which may be seen in the windows of the shops in Charing Cross Road, where "rubber goods" may be obtained by those who want them.

On the fourth leaf is written in an uneducated late eighteenth century hand, "A resite for a Waste. 1 ounce of Hartshorn shavings, 1/2 oz. of Isinglass, 2 calves feet, 3 pints of cows (?) milke. Stew the calves feet in a jare in the oven, then strayne through a cloath. Tack a Tee cuppe 2 or 3 tims a day." Not bad food for a consumptive. About the middle of the book two pages are taken up with remedies preservative "against the lues Ungarica or the new disorder raging through England." These are chiefly taken from Dr. Whitmore's book. This would be Humphry Whitmore, M.D.Oxon., 1648, and Hon. F.R.C.P., 1664. What the disease was is unknown, but as the remedies were chiefly of a stimulant kind, and bleeding only recommended to the plethoric and robust, it was probably influenza, certainly not plague, as that had been and was too well known. The writing is in the same hand as that describing the signs of pregnancy.

In conclusion, we have here a little bit of the flotsam cast up on the shores of Time, bringing to mind that even in the time of the Civil War the careful practitioner carried about with him what is equivalent to Martindale's or Squire's compendia, adding thereto from time to time some useful prescription or bit of knowledge which would stand him in good stead when up against a difficulty whether of a single case or, as in the last quotation, an epidemic.

F. W. C.

* The arms of the Boraston family are given in *Arch. Cant.*, xvii, p. 242: "Quarterly arg. and sab. on a bend between 2 cotises gules, 3 crosses formy fitchy, or. Crest, out of a mural coronet sable a griffin's head, or, gorged with a fess between 2 bars gemel gules."

THE METROPOLITAN ASYLUMS BOARD.

REVIEW OF THE YEAR 1928-29.

"*Morituri te salutant*" might be inscribed on the orange cover of the report of the Metropolitan Asylums Board for 1928-29,[1] for, as the Board announces, in a tone of regret if not of complaint, the functions which it has discharged for more than sixty years are to be transferred to the London County Council. The Board points out that since its inauguration it has enlisted the services of a large number of men and women who have devoted themselves to the work of providing, maintaining, and extending where necessary the public hospitals required by London for infectious diseases, tuberculosis, and mental cases; that it has organized an ambulance service which last year conveyed nearly 100,000 patients; and that it has under its control about 25,000 hospital beds, and in times of pressure employs a staff of 10,000 persons. The Board is naturally anxious to have it placed on record that its disappearance with forthcoming changes in local government is not due to any shortcomings; on the contrary, a tribute has been paid to the efficiency of its organization by the late Minister of Health and by the London County Council, which is the absorbing body. The Board believes that this absorption may well be viewed by the people of London with regret, and it observes that under the "guillotine" no opportunity was afforded in the House of Commons for a discussion of the provisions of the Local Government Bill as affecting London, and consequently no reference could be made in Parliament to the Board's work.

Infectious Diseases.

Turning from the indefinite future to the very definite and documented past, we have the usual tables of statistics relating to cases dealt with by the Board. The following figures show

[1] Metropolitan Asylums Board. Annual Report for the year 1928-29. Office of the Board, Victoria Embankment, E.C.4. 5s.

the admissions to its hospitals for the commoner infectious diseases, with the corresponding figures for 1927:

	1928.		1927.	
	Cases Admitted.	Deaths.	Cases Admitted.	Deaths.
Diphtheria	8,931	335	9,155	370
Diphtheria (Bacteriological)*...	1,037	9	1,165	11
Measles	7,307	561	2,350	123
Scarlet fever	13,065	81	11,470	64
Whooping-cough	1,455	122	1,888	217

*Cases in which bacteriological evidence of diphtheria has been found, but no clinical evidence, such as inflammation of throat or nose.

The chief point calling for notice is the large number of whooping-cough cases, which, though below the figure for 1927, is nearly double the yearly average since 1911, when the Board was first empowered to admit this disease into its hospitals. The figures for 1929 bid fair to be higher still. The greatest pressure on the accommodation for whooping-cough cases occurred on April 3rd last, when there were 1,222 such cases in the hospitals; the previous highest number at any one time was 789 in 1911. The mortality percentage of patients treated for whooping-cough was 9.33, compared with 7.17 for measles and 0.63 for scarlet fever. The mortality for scarlet fever was much the same as for 1927, though the personal observation of the chief medical officer of the infectious hospitals service, Dr. F. H. Thomson, is that the type of scarlet fever prevalent in 1928 was less benign. Dr. F. M. Turner, medical superintendent of the South-Eastern Hospital, makes a comparison between the scarlet fever cases at that hospital in 1903 and 1928; in the former year the case mortality was 3.11 per cent., and in the latter year 0.55, and he states that scarlet fever now is definitely less severe, the duration of the fever shorter, and the maximum temperature lower. The case mortality of diphtheria in 1928 was 3.66, the lowest yet recorded. With regard to measles, it is noted that the case mortality during the epidemic of 1927-28 was much higher in children under the age of 2 than in children of older years. Dr. Thomson states that it is almost certain that in the course of every epidemic of measles in London a time will come when the pressure on the hospital accommodation will be such that not all cases can be admitted. At present, when a shortage of beds becomes imminent, the medical officer of health, on whose recommendation alone in that event such cases are accepted, bases his selection rather upon the type of home than the type of case. While fully realizing that the type of home influences the case mortality of measles, Dr. Thomson says that it should not be forgotten that the case mortality under 2 years is very high, and therefore the age of the patient should also be a factor in the selection of admissions.

The Small-pox Outbreaks.

The number of admissions for small-pox during 1928 was 288, and there were 2 deaths. The highest figure for monthly admissions (84) was reached in June. The disease throughout was characterized by a low degree of toxicity and infectivity—that is to say, it was a type highly amenable to the influence of vaccination, and a type against which infantile vaccination affords a much more prolonged immunity than in the severe toxic type of the disease to which London has been accustomed in times gone by. "It is possible to say," proceeds the report, "that the experience of the past year has shown that the subtoxic type of the disease can be kept under control by vaccination even more easily than the more severe type, and that it is precisely in those districts in which vaccination is neglected subsequent to the appearance of the disease, and where the innocuous character of the disease induced the people to refuse to submit themselves or their children to vaccination, that widespread prevalence has occurred." The danger of neglect is illustrated by the recent intercurrence of the more severe and deadly type of infection, imported to London from Bombay in April last amongst the crew and passengers of a large liner. In connexion with this invasion, fourteen patients were admitted to hospital, of whom two died, while six of the others suffered attacks so severe as to put life in jeopardy. The deaths occurred in patients who had refused the protection of vaccination subsequent to exposure to infection, and one of them came from West Ham, where the subtoxic type has been very prevalent, and vaccination has been neglected. This patient was the only instance of the infection passing from a member of the ship's company to one of his family. During the first four months of the present year no fewer than 661 patients have been admitted for small-pox (370 of them in the month of April), and nearly half of them from West Ham.

Mental Diseases: Tuberculosis.

The average annual number of direct admissions of mental cases to the Board's institutions during the past three years has been 1,534; these include cases under the Lunacy and under the Mental Deficiency Acts, feeble-minded patients uncertified, uncertified aged poor, and sane epileptic patients. The demands of the metropolis on the Board's accommodation for cases of mental defect have been increasing for some years past, so that it has now become necessary to give notice to extra-metropolitan authorities to remove as soon as possible their mental defectives who are maintained in the Board's certified institutions; over sixty authorities and 1,400 patients are affected by this order. A unit of 100 beds has been maintained since 1925 at the Northern Hospital for the reception of children suffering from the after-effects of encephalitis lethargica. Now, following representations from certain metropolitan boards of guardians, it has been decided to reserve 50 beds at the same hospital for the treatment of adults suffering from the same condition, and to reduce to 75 the beds available for persons under 16.

During the year under review 3,631 cases of pulmonary tuberculosis were admitted to the Board's institutions, which is about the same figure as for 1927. The average duration of stay again increased at all the institutions for adults, the mean figure being now 22 weeks in sanatoriums and 18½ weeks in hospitals for advanced cases. A symposium is published in which the medical superintendents pool their experiences of treatment by gold salts. While selected cases may benefit, the general tenor of the report does not appear very encouraging. Surgical methods of treatment are being more widely used, and the Board has taken the step of appointing a chest consulting surgeon.

Special Clinics.

Mr. Comyns Berkeley, the honorary director, reports on the first six months' working of the radium centre for the treatment of carcinoma of the uterus, primarily the cervix. This centre, for which radium has been purchased at a cost of over £4,000, is at the North-Western Hospital. Up to the present 54 patients have been admitted, of whom 33 have completed their treatment. All cases of cancer received at the centre, if not obviously in the last stages of the disease, have been treated, if only as a palliative measure. No indication can be given as yet of the results, but Mr. Berkeley believes that if medical practitioners were allowed to send their patients direct to the centre, as obtains in fever cases, instead of through the Poor Law hospitals, many more patients would be received in the early stages, and therefore the lives of many more women would be saved. The majority of such cases are now sent to the general hospitals, where they may have to wait some time before admission, and meanwhile the disease is progressing.

The 208 cases admitted to the wards set aside for the treatment of uterine infection are reviewed by Mr. James Wyatt. He states that, with regard to septicaemia, nothing specific has been found that appears to help in any way, and in cases where the blood culture is positive the mortality seems to be almost 100 per cent. There is no doubt, in his opinion, that some cases are infected by manipulations, but this certainly does not account for all. He believes that the organism is sometimes air-borne from the nose or mouth of the attendant, and suggests that a veil should be worn at every confinement. The Board has decided to concentrate all the acute cases of puerperal fever and puerperal pyrexia in future at the North-Western Hospital, instead of at two or three hospitals as hitherto, and arrangements have also been made for the assistant director of research and pathological services to be in frequent attendance to see new cases and discuss with the visiting obstetric consultant what bacteriological measures should be adopted.

The report embodies the usual large number of contributions by members of the staff, some of them in the form of notes on special cases, others relating to original investigations.

Scotland.

Bicentenary of the Edinburgh Royal Infirmary.

The bicentenary of the opening of the Royal Infirmary of Edinburgh fell on August 6th, and on that day an interesting memento of the occasion in the form of an illustrated commemorative card was presented to all the patients and members of the staff. The public celebration of the bicentenary has been deferred till early in October, when it is proposed to have a thanksgiving service in St. Giles's Cathedral, followed by a public meeting in the Usher Hall, and to launch an extension appeal for £300,000.

The remarkable story of the growth of the Royal Infirmary has been sketched in a most interesting and attractive small volume by Dr. A. Logan Turner, which is being printed by Messrs. Oliver and Boyd, and will be sold eventually in aid of the Infirmary funds. Dr. Logan Turner recalls that, in the medical history of Scotland, the dawn of the eighteenth century witnessed the inception of two great interdependent movements—the foundation of her schools of medicine and the establishment of the voluntary hospital. As befitted the capital of the country, both these movements were initiated in Edinburgh, where they first took practical shape. The Edinburgh School of Medicine began its long and distinguished record in 1726. In 1721 John Munro, the Deacon of the Incorporation of Surgeons, who, as was then the fashion, had studied in Leyden, issued a pamphlet in which he set forth the great necessity of founding a hospital, not only for maintaining and curing the sick poor, but also as a means of imparting clinical instruction. The scheme languished, but received a fresh impetus in 1725, when the physicians called a public meeting and made an appeal for subscriptions. In due course a sum slightly exceeding £2,000 was raised, and this was deemed sufficient to justify action being taken. In December, 1728, at a meeting of the contributors, twenty of their number were elected managers, and the rules of management were drawn up. A small house was rented at the top of Robertson's Close, which linked the Cowgate on the north with a thoroughfare (now known as Infirmary Street) giving approach from the west to the grounds of the old Black Friars' Monastery. After the provision of the necessary furniture, a gentlewoman was appointed as mistress or housekeeper at a salary of £5, along with one servant or nurse for the care of the patients. On August 6th, 1729, the hospital was ready for the admission of patients, and at the end of the first month the six beds which it contained were occupied. From the outset no restrictions were placed upon admission to the hospital; the first patient came from Caithness, and others during the early months from Peterhead and the Island of Mull. In the first year 35 patients were treated. It is of interest to note that ague or malaria is mentioned four times as one of the diseases treated. The cost of upkeep during the year was about £98.

With the grant of a charter by King George II in 1736 the Infirmary entered upon a new phase of its progress. The change of status had the effect of increasing public interest, and in August, 1738, the foundation stone of a new building was laid with appropriate civic ceremony in Infirmary Street. The east wing was opened in 1741, and the whole scheme was completed in 1745. During the fighting in the rebellion of '45 the hospital was extensively used by the military authorities for the treatment of wounded soldiers. There followed in the new building a notable development in medical education in Scotland, for Professor John Rutherford and his colleagues introduced the Leyden method of clinical teaching, which, as developed by them, became one of the distinctive methods of instruction in the Edinburgh School. In 1749 the managers issued instructions that a ward should be placed at the disposal of Professor Rutherford to accommodate those patients—not exceeding ten in number—whom he proposed to use as the text of his lectures. Early in the nineteenth century the question of enlargement again became urgent, and opportunity of effecting an extension arose in 1828, when the pupils of the High School were transferred to the Calton Hill. A sum of £7,500 was paid by the managers to the town council for the High School buildings just vacated, and these were adapted and furnished as a surgical hospital with 72 beds, which later was to be associated with the great work of Syme, Simpson, and Lister. This part of the old Infirmary is still standing, and is now the engineering department of the University.

With the passage of years the buildings at the foot of Infirmary Street became totally inadequate, and plans for a new building were prepared. There was much controversy as to whether it should be erected on the site of the old or whether a new neighbourhood should be chosen. Eventually the site in Lauriston was selected, and there sprang up the great baronial pile we know to-day. Altogether £350,000 was expended on the new Infirmary, and it was a noteworthy achievement on the part of the people of Scotland that the hospital was opened with a debt of only £50,000. The foundation stone had been laid in 1870 by the Prince of Wales, and the formal opening took place in 1879. The present year, therefore, marks not only the bicentenary of the opening of the first building, but the fiftieth anniversary of the opening of the present buildings. On October 31st, 1879, some 240 patients were transferred in cabs and other vehicles from the old quarters to the new. The accommodation was 500 beds, which had since been doubled. In 1770, 1,302 patients were treated; in 1805 the number had risen to 2,103; last year 19,680 indoor patients and 62,085 outdoor patients were treated. In 1730 the upkeep cost £97 19s. 7d.; last year it was £136,831. The latest additions to the equipment of the Infirmary are the radiological department, which cost £50,000, and was opened by the Duke of York in 1926, and the clinical research laboratory, presented at a cost of £35,000 by the Rockefeller Trust. The most recent development in connexion with the institution is the reconstruction of the mansion house of Beechmount, Murrayfield, as a radium institute for Edinburgh and the south-east area of Scotland; this institute will be under the management and direction of the Infirmary board. But still another extension is being made, as mentioned previously. George Watson's College and grounds, which adjoin the Infirmary, have been acquired at a cost of £90,000, and it is proposed to erect here a maternity and gynaecological hospital with accommodation for 240 patients, and a new nurses' home. The ultimate cost, it is estimated, will be about £300,000.

Whatever the future has in store for the Royal Infirmary, it can be claimed that, since its humble and modest origin two hundred years ago, it has continuously discharged the double function which its founders, just prior to 1729, desired that it should fulfil—"the saving and restoring to health members of society," and the education of the future practitioner of medicine.

Research at the Glasgow Children's Hospital.

In the annual report of the Royal Hospital for Sick Children, Glasgow, for the year 1928, a special appeal is made for a research fund of £20,000. It is urged that an important function of such a hospital with its very large clinical material is research into the causes and the best means of preventing and curing the diseases of infancy and childhood. In close association with the University, where valuable foundations exist for scientific workers in diseases of children, the hospital has to provide the requisite facilities, skilled assistance, accommodation, expensive apparatus, etc., to enable these investigators to carry out their work. The directors feel that the ordinary funds of the hospital should not be called upon to bear this burden, and the research fund is required to meet this form of expenditure. Another university lectureship associated with the hospital has recently been founded, to be known as the Gardiner Research Lectureship on the Pathology of the Diseases of Infancy and Childhood, and Dr. John S. Blacklock, pathologist to the hospital since 1924, has been appointed to hold this position, and Dr. Katherine J. Guthrie to be assistant pathologist. These recent appointments only serve to accentuate the position outlined above, and the success of the appeal for the research fund becomes a matter of urgency.

Health of Dundee.

The report for 1928 of Dr. W. L. Burgess, medical officer of health for Dundee, begins with the statement that the year showed a marked improvement in the vital statistics compared with the previous years, an improvement which was due almost entirely to a reduced prevalence of certain of the epidemic diseases. The death rate was 15.1 per 1,000, as against 16.9 in 1927. This compares with 13.7 for Edinburgh and Glasgow (*Journal*, July 13th, p. 71, and July 20th, p. 120). The birth rate was 20.3, which is the lowest recorded for the city except for the war years. The corresponding figures for Edinburgh and Glasgow were 17.3 and 20.62. The infantile mortality rate was 102 per 1,000 births, the second lowest on record. Edinburgh's infantile death rate was 75 and Glasgow's 107. Dr. Burgess remarks that the conditions prevailing in Dundee are particularly hard on infant life. The tuberculosis death rate was 1.05 per 1,000, compared with 1.16 in 1927. The number of deaths from malignant disease, 338, is greater than in any previous year. There were 623 cases of diphtheria notified, as against 1,023 in 1927, when there was a severe epidemic; the mortality was 4.8 per cent. Each death from diphtheria occurring during the year has been the subject of inquiry and report. The evidence provided by these reports suggests that a very marked decline in the number of deaths from diphtheria would follow a more thorough understanding on the part of the public of the nature of the infection. The year's experience also provides further proof that recovery depends mainly on the prompt recognition of the disease and the immediate administration of antitoxin. Small-pox again appeared in the city, but was confined to a small outbreak of five cases.

New Haddington Hospital.

The laying of the memorial stone of the Haddington and District Cottage Hospital took place on August 1st, the ceremony being performed by the Earl of Wemyss, Lord-Lieutenant of the county. The hospital is being erected on a splendidly elevated site to the north of the burgh, commanding a fine panoramic view of the town and Tyne valley, as well as the Lammermuir ranges to the south. Provost George Rattray, chairman of the hospital committee, presided, and remarked that there had been a very generous response to the appeal for funds. A donation of £8,000 had been made by Mr. John Vert, a native of the burgh resident in the United States. Another native in America, Mr. Horsburgh, had forwarded a cheque for £1,000. Altogether £16,000 had been received. In addition, Mr. Henry Veitch had given the excellent site; the builder, Mr. Richard Baillie, had generously offered to build the front and sides of the hospital with stone, in place of brick, taken from Lord Wemyss's old mansion house, Amisfield; and Lady Wemyss and other ladies had contributed certain furnishings. On the motion of Lord Polwarth, a vote of thanks was awarded to the Earl of Wemyss, and on the call of Dr. W. R. Martine a similar compliment was accorded to Provost Rattray.

Preservatives in Cream.

Speaking recently at the annual meeting of the Galloway Creamery, Ltd., at Stranraer, Mr. F. T. Ferguson, chairman, said that since the Order eliminating preservatives from cream the company had found that half a million gallons less milk were required for their cream trade. That amount had either to be thrown into the liquid milk market, where it was not wanted, or manufactured into cheese, where it was not wanted either. Conferences and pleadings with the Public Health Department had been of no avail. He had received a letter from Major Dudgeon, member of Parliament for Galloway, in which he said that several Scottish members of Parliament had been going into the question of getting the order rescinded, and they were to discuss the matter fully with a responsible representative of the Ministry of Health. The Galloway Creamery, the chairman continued, had had to make 7,000 more cheeses than in the previous year, and with the estimated stocks of New Zealand cheese more than double and Canadian stocks two and a half times more than a year ago, there was no market for this large quantity.

Central Midwives Board for Scotland.

At the recent examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, out of 123 candidates who appeared for the examination, 110 passed. Of the successful candidates, 35 were trained at the Royal Maternity Hospital, Glasgow; 27 at the Royal Maternity Hospital, Edinburgh; 9 at the Royal Infirmary, Dundee; 6 at the Maternity Hospital, Aberdeen; 10 at the Elsie Inglis Memorial Hospital; 5 at Stobhill General Hospital; 2 at Barshaw Maternity Hospital; 4 at Motherwell Maternity Home; 3 at the County Hospital, Bellshill; 3 at the Cottage Nurses Training Home, Govan; 3 at the County and City of Perth Royal Infirmary.

England and Wales.

London Coroners: Proposed Alteration of Districts and Revision of Salaries.

NINE coroners at present officiate in the County of London, exclusive of the City of London, which has its own coroner. There are seven districts to which the coroners are appointed by the London County Council, and there are also five franchise districts, to which the coroners are appointed by other bodies or persons, but in the case of three of these franchise districts the coroner is also a county coroner. The five districts are Westminster, where the appointment is by the Dean and Chapter; Southwark, where it is by the City Corporation; the Duchy of Lancaster (Clapham) and the Duchy of Lancaster (Savoy), where the Crown appoints, and the Liberty of the Tower, where the appointing person is the Constable. The abolition of these franchise districts has been advocated by the London County Council for thirty years. Under the recent Coroners (Amendment) Act they will be absorbed into the county for coroners' purposes as and when vacancies occur. The London County Council, therefore, has been considering the division of the county under the new and more uniform arrangement which will eventually come about. It is proposed to divide the county into six districts, having regard to recognized electoral areas, the situation of the larger hospitals, travelling facilities, inquest and post-mortem accommodation, and traffic conditions. The districts will be as follows:

District.		Metropolitan boroughs.
Western ...	...	Hammersmith, Fulham, Battersea, Wandsworth, and Chelsea.
Central ...	...	Westminster, St. Marylebone, Paddington, Holborn, Finsbury, and Kensington.
Eastern ...	...	Shoreditch, Bethnal Green, Stepney, and Poplar.
Northern	...	St. Pancras, Islington, Stoke Newington, Hackney.
Southern	...	Lambeth, [illegible] wark.
South-Eastern ...		Bermondsey. [illegible], Greenwich, and Woolwich.

The present North-Eastern and South-Western districts will disappear, the former being divided between the Eastern and Northern, and the latter between the Southern and Western, while all the franchise districts will be absorbed according to their geographical areas. This rearrangement involves a reconsideration of salaries. The salaries received by the coroners at present, all of which are paid by the London County Council, vary from £1,041 to £1,500, and in addition each county coroner receives an allowance of £100 during the council's pleasure. The new salary proposed to be fixed is £1,700 inclusive. In arriving at this figure it is stated that regard has been paid to the fact that London coroners are required to possess both medical and legal qualifications, and to bear expenses connected with their office estimated to amount to £250 for each coroner yearly. The question of pensions for coroners has also been raised. Two of the present coroners are over 70 years of age, and it is thought that preliminary steps

should now be taken in order that there may be the least possible delay in making a change. Under the Act power to pay pensions to coroners is conferred upon the council. The pensions laid down in the Act are more liberal than those normally granted out of the London County Council's superannuation fund, but in view of the qualifications now required for the position of coroner, combined with the comparatively advanced age at which the majority of them are appointed, it is felt that coroners are not as a class entirely comparable with the general body of the council's staff. It is proposed to adopt the scale of pensions set out in the first schedule of the Coroners Act, with the modification that ten instead of five years' service be the qualifying period. A coroner reaching the age of 65, or on being permanently incapacitated, will be granted a pension at the rate of ten-sixtieths of his salary, with the addition of one-fortieth of his last annual salary for each completed year of service after five years, provided that no pension shall exceed two-thirds of the last annual salary.

East Ham War Memorial Hospital.

What was formerly the East Ham (Passmore Edwards) Cottage Hospital in Shrewsbury Road, founded in 1902, with twenty-five beds, has recently been converted into a general hospital containing 100 beds, as a memorial to the two thousand men belonging to this county borough who gave their lives in the great war. The reconstructed hospital, the only voluntary institution of its kind in this crowded district, is of very pleasing architecture and excellent planning. The ward blocks are so arranged, with their main axes north and south, as to secure the maximum circulation of air and sunlight, and they overlook extensive grounds which are available for the use of the patients. Accommodation for private paying patients is provided, and there is included a very well-equipped operating theatre and x-ray department, while the kitchens and other offices are all in the most modern style. In the entrance hall, on memorial tablets, are inscribed the names of East Ham's war heroes. The capital cost of the building and equipment is £75,000, towards which £60,000 has been subscribed, mainly by way of small local contributions, and a further £2,000 has been promised by the King Edward's Hospital Fund. It is being put to East Ham as a point of honour that the major portion of the cost of maintenance, which will be at least £10,000 a year, should be met from local sources. Although the hospital has been receiving patients since the beginning of the year, the formal opening did not take place until the close of last month, when Her Majesty the Queen paid the hospital a visit, made an extended tour of inspection, and spoke to many of the patients. Sir Hugh M. Rigby, honorary consulting surgeon to the hospital, and Dr. Maurice B. Shaw and Mr. A. E. Mortimer Woolf, honorary senior physician and honorary senior surgeon respectively, were among those presented.

Ante-natal Clinic at Guy's Hospital.

The annual report of Guy's Hospital for 1928 recalls that it is now ten years since the governors, through the generosity of the trustees of the late Mr. Leopold Salomons, instituted a welfare centre in connexion with the hospital. Provision was made in this centre for an ante-natal clinic at which mothers could receive advice during pregnancy, and for an infant welfare centre for advising mothers as to the general care of their children until the age of 5. The essential principle of the ante-natal scheme was that mothers should, throughout their pregnancy, be under the direct personal supervision of the assistant obstetric surgeons, who would eventually be responsible for their care during confinement, either at their own homes or in the maternity ward of the hospital. The result of the institution of this ante-natal clinic has been to revolutionize the midwifery practice of the hospital. Unforeseen complications, which formerly had to be dealt with as emergencies when labour had actually begun, are now provided for, and can be dealt with in good time; there are now available from the clinic full notes for the guidance of every hospital doctor or midwife who goes out to attend a mother in the maternity district. The maternal death rate among all the confinements attended by the hospital last year, both in the maternity ward and in the patients' own homes, was only 0.56 per 1,000, or one death in 1,782 cases. In view of the widespread interest now being taken in the subject, and the fact that the average mortality among mothers throughout the country is about 4 per 1,000, the governors feel that they can but congratulate themselves upon the success of the Guy's Hospital maternity district as proving the value of a properly organized ante-natal centre.

The Excursion to Colwyn Bay.

The very last event of the Annual Meeting of the British Medical Association at Manchester, briefly mentioned on August 10th (*Supplement*, p. 112), was a visit to Colwyn Bay, in which about seventy members participated. On arrival at this pleasant North Wales resort the visitors were conveyed to Penrhos College, in the beautiful hall of which they were entertained to lunch. The hosts of the day were the Colwyn Bay Medical Society, who had taken over the privilege from the North Carnarvon and Anglesey Division. Dr. R. E. Lord, J.P., president of the society, occupied the chair, and was supported by Dr. D. I. Currie and Dr. Edith Shaw, honorary secretaries, and others. Lord Colwyn and Miss Wainwright, principal of the college, spoke a few welcoming words, which were responded to on behalf of the visitors by Mrs. Burgess, wife of the President of the British Medical Association, and by Dr. Bosdin Leech, one of the general secretaries of the meeting, who acted as cicerone. After luncheon the visitors were taken on a motor tour, beginning with the high land at the back of the town, proceeding to the picturesque town of Llanrwst, and touching on the return journey Trefriw, with its iron and arsenic mineral spring, and the old town of Conway. Several of the visitors returned direct to their homes by earlier trains, but those who remained, and returned to Manchester, enjoyed the further hospitality of their Colwyn Bay friends at tea.

The Central Public Health Committee for London.

It is proposed that the new Central Public Health Committee for London, upon which very important duties in relation to hospitals and medical services will devolve under the Local Government Act, shall consist of twenty-five members, of whom eighteen shall be members of the London County Council, the parent body, and seven shall be co-opted members. This committee may, under the Act, appoint subcommittees consisting wholly or partly of members of the committee as it sees fit.

Correspondence.

ACUTE ANTERIOR POLIOMYELITIS.

SIR,—I do not think it would be superfluous to remind ourselves that an epidemic of acute anterior poliomyelitis is very liable to occur at this particular period of the year. It will be remembered that the epidemic of 1926 started that summer, and reached its height during the drought. During that epidemic I saw over 150 cases, chiefly in Essex. I was fortunate enough to treat most of them from the very onset of the disease. This was at their own homes, or in fever hospitals, or at the various hospitals to which I am attached. In addition to the ordinary orthopaedic treatment it was also possible to give suitable cases the serum from convalescent or chronic cases of the disease, with encouraging results.

History may be repeating itself, as I have already seen a number of acute cases within the last few weeks. I would therefore plead that the orthopaedic surgeon should be allowed to treat the patients, wherever they may be, in fever hospital or elsewhere, from the moment of the onset of the disease, thereby following out, to the minutest detail, the teaching of Sir Robert Jones, that the affected muscles should have *immediate*, complete, and absolute rest in the orthodox positions necessary for optimum utility after the acute stage has passed.—I am, etc.,

London, W.1, Aug. 7th. B. WHITCHURCH HOWELL.

POST-VACCINAL ENCEPHALITIS.

SIR,—The disturbing problem of the occurrence of acute nervous diseases after vaccination takes on a new aspect with the intimation that much of the lymph which is sold to medical practitioners is obtained from rabbits and not from the calf.

An examination of the literature of experimental epidemic encephalitis shows many conflicting results obtained by different observers. McIntosh[1] thinks that rabbit inoculation is of the greatest value in confirming a diagnosis after death, using emulsions made from the basal nuclei. Levaditi and Hervier[2] also found that the virus of encephalitis is pathogenic to rabbits and guinea-pigs, whilst Veratti and Sala[3] were unable to obtain any results in rabbits with a similar virus. On the other hand, McCartney[4] examined the brains of 372 rabbits, some of which were healthy and others of which were being used for experiments not connected with epidemic encephalitis. It was found that 70 to 76 per cent. of these animals showed lesions which could be mistaken for those of encephalitis — for example, perivascular infiltration, meningeal haemorrhages, etc. Attempts to transfer the lesion to other rabbits failed. It is concluded by this investigator that the "accidental" cerebral lesion in the rabbit is of a wide variety and of so frequent occurrence as to be regarded as existing before any experimental procedure. Da Fano[5] agrees with these observations, and believes that this "spontaneous" form of encephalitis or encephalomyelitis may occasionally occur in circumscribed epizootics.

Whatever may be the diagnostic value of rabbit inoculation as regards epidemic encephalitis, it appears almost certain that if rabbits do not have an encephalitis of their own they are susceptible to such a disease, and the wholesale preparation of lymph from susceptible animals is a probable explanation of the 62 reported cases of post-vaccinal encephalitis in this country.

I bring these views forward in the hope that they will lead to further research in order to give us evidence as to whether we may or may not rely upon the lymph which is usually supplied commercially. To those of us who are called upon by a public which is well informed by the press to decide as to whether vaccination is perfectly safe or not, the possibility, however remote, of nervous complications is disquieting. The possible, though statistically infinitesimal, danger in vaccination is quite great enough to allow one to acquiesce tacitly in the conscientious objection of the parent to allow a child to undergo a risk which might lead to a tragic future. The provision of lymph which is beyond reproach is not only necessary for the repute of preventive medicine, but also for the welfare of the community.—I am, etc.,

RICHARD I. POSTON, M.D.,
Honorary Assistant Surgeon, Oldham Royal Infirmary.

Manchester, Aug. 8th.

BACTERIAL FILTRATES OR "ANTIVIRUS" THERAPY.

SIR,—After two years' personal experience of the therapeutic action of bacterial filtrates, I feel it would be unfortunate, as Mr. R. F. Hunwicke remarked in your issue of June 15th (p. 1100), if indifferent criticism discouraged a more extensive trial of bacterial filtrates in practice. I purposely avoid the term "antivirus," as Besredka thereby connotes specific, selective, and local immunizing properties, all of which are still subjects of controversy. Properties inhibitory to bacterial growth are undoubtedly present in bacterial filtrates, but that they are specific has not been proved by experiments *in vitro*. Acidity of the medium resulting from biological activity is, no doubt, one of the inhibitory factors of pneumococcal, streptococcal, staphylococcal, and *B. proteus* filtrates, the *p*H of which ranges from 4.5 to 6.5, but acidity does not operate in the case of filtrates prepared from diphtheroid and Friedländer bacilli, the *p*H of which was found to be 7 and 8 respectively. Apart, however, from the debatable problems of selective action and local immunity, I venture to suggest, from the apparently benign action of filtrates on septic tissues, that filtrates act in a dual capacity—namely, as a bactericidal agent and as a tissue stimulant. The local immunity aspect has been somewhat laboured experimentally, but as regards the possible beneficent action of amino-acid products of the medium on the tissues little has been said.

The medium used by myself is trypsinated broth with glucose added, which, acted on further by the biological activities of bacterial growth, may possibly be broken down into such radicles as may be more readily assimilated by the locally infected tissue cells, and to their advantage. In this respect filtrates may act in an anti-infective as well as an antibacterial capacity. I experimented with trypsinated broth alone in control septic cases, using it as a wet dressing, but, as was to be expected, it was found wanting. On the other hand, the healthy skin of guinea-pigs, to which were applied plain broth compresses, was protected locally against subcutaneous injections of *Staphylococcus aureus*, according to Friedländer and Toomey. Plain broth compresses were stated to produce a local cellular reaction in the form of proliferation of clasmatocytes, and exudation of polymorphs and small mononuclears, which may be interpreted as an anti-infective response.

Although the tenets of immunology may not be satisfied by Besredka's "antivirus," this does not detract from the therapeutic value of bacterial filtrates. The main theme of this letter, however, is merely to advocate a wider trial of bacterial filtrates in acute infections such as erysipelas, and in chronic infective conditions, when evidence of their value, "apart from pious opinion," may then be obtained.—I am, etc.,

G. BUCHANAN, M.D., D.P.H.,
Superintendent, Routine Division, South African Institute for Medical Research.

Johannesburg, July 17th.

PHYSIOLOGICAL STUDY OF ASTHMA.

SIR,—I have read with interest the letters from Dr. Harry Campbell and Dr. P. Watson-Williams relating to the abstract of Brodie and Dixon's paper which you published on July 13th (p. 68).

Dr. Dixon is at present in South Africa, and will not have seen the correspondence. I feel that certain criticisms contained in Dr. Watson-Williams's letter of July 27th (p. 164) can and should be answered. As a colleague of Dr. Dixon's, I shall endeavour to do so; it will, of course, be clear that the views I express do not, in the circumstances, commit Dr. Dixon in any way.

The evidence for the normal rhythmical contraction and dilatation of the bronchioles is indirect, but, as Dr. Watson-Williams suggests, fairly strong, and is well summarized by Macklin (*Phys. Reviews*, 1929, vol. ix, p. 1). There do not appear, however, to be at present any grounds for Dr. Watson-Williams's assumption that "the asthmatic paroxysm is merely an exaggeration of the physiological bronchiolar dilatation on inspiration and contraction on expiration."

An inspection of the tracings obtained by Brodie and Dixon, and published in their original paper, makes it clear that they were dealing with steady states of bronchial constriction and dilatation; their interpretation of their own experimental findings admits of no question. On the other hand, they were dealing, not with clinical asthma, but with an experimental condition which resembled it very closely indeed. They would probably not deny, in theory, the possibility of rhythmical contraction and dilatation playing a part in the clinical condition; but, in the absence of any direct proof of its occurrence, they would presumably consider it unnecessary to invoke it to explain phenomena already quite satisfactorily accounted for by other and directly observable factors.—I am, etc.,

ERIC HOLMES,
Pharmacological Laboratory, Cambridge.

August 12th.

[1] McIntosh: *Brit. Journ. Exper. Path.*, 1923, 4, 24.
[2] Levaditi and Hervier: *Bull. de l'Inst. Pasteur*, 1920, 84, 411.
[3] Veratti and Sala: *Boll. d. Soc. Med. di Pavia*, 1922, 34, 239.
[4] McCartney: *Journ. of Exper. Med.*, 1924, 39, 51.
[5] Da Fano: *Med. Science*, 1924, 10, 355.

SIR,—In his letter in your issue of August 10th (p. 277) Dr. Harry Campbell, while maintaining his own views, kindly admits "that Dr. Watson-Williams's . . . hypothesis would explain . . . the phenomena of the asthmatic attack." May I remind him that this physiological dilatation of the bronchioles on inspiration and contraction on expiration was visibly demonstrated by Dr. W. Hudson's radiograms that he showed at the discussion on asthma on July 26th at the Annual Meeting of the British Medical Association at Manchester. In the light of these facts we can explain many clinical problems bearing on the questions at issue. For example, we may turn to Drs. Evan Bedford and Joules's record of bilateral spontaneous pneumothorax which also appeared in the issue of August 10th (p. 240). When both lungs had collapsed the intrapleural pressure registered over 30 cm. of water in the manometer, which was reduced by aspiration, and ere long first one and then the other lung became fully expanded.

Here the alternating dilatations and contractions of the bronchioles, instead of keeping the lung expanded, went on pumping air through a small perforation in the visceral pleura into the intrapleural sac till the air therein was under high pressure and had to be aspirated. But when the perforation healed, the same bronchiolar mechanism dilated the lungs till their expansion was complete. What happened at the patient's birth causing his solid newborn lungs to expand happened again when his lungs were almost completely collapsed—his bronchiolar dilatations on inspiration and contraction on expiration brought about the alveolar inflation and lung distension on both occasions. —I am, etc.,

Bristol, Aug. 12th. PATRICK WATSON-WILLIAMS.

TUBERCULOSIS OF THE LARYNX.

SIR,—In the conjoined Sections of Oto-Laryngology and Tuberculosis at the recent meeting in Manchester I drew attention to two points in relation to tuberculosis of the larynx which are, in my opinion, of such importance that I ask your permission to mention them here, while reserving any arguments in support of them to some future occasion when the pressure on your space is less heavy.

The first is the *microscopical examination (biopsy) of a portion of tissue* removed from the larynx in cases (and there are such) in which there is a great element of doubt as to the diagnosis between tuberculosis and, say, carcinoma. The second is that *pain in tuberculosis of the larynx is in general a strong indication for the use of the galvano-cautery*, not a contraindication.—I am, etc.,

London, Aug. 12th. JAMES DUNDAS-GRANT.

PERFORATION OF DUODENAL ULCER IN AN OCTOGENARIAN.

SIR,—Several cases have been recorded recently of successful operations for perforation in persons of 70 or more years of age. But I think that, during the ninth decade, such cases must be more uncommon.

About ten years ago I operated on a man, aged 83, for perforated duodenal ulcer. He was healthy and fairly robust for his age. Fortunately I saw him very soon after the perforation had occurred, and was able to transfer him to a nursing home, and operated with a minimum of delay. He made an uneventful recovery, left the home in a fortnight, and lived for another four years without any gastric discomfort.

—I am, etc.,

Ipswich, Aug. 10th. HERBERT H. BROWN.

FRACTURE OF ANTERIOR ILIAC SPINE.

SIR,—In your issue of June 15th (p. 1077) Dr. James Crawford reports a case of avulsion of the anterior superior spine of the ilium by the action of the sartorius in running. It is surprising that such a long and attenuated muscle should have power enough to do this, but I had an exactly similar case in 1926. My patient, a youngster of 18, while running in a hundred yards race, "felt something break at the front of his right hip, and distinctly heard a grating of bone." He finished, *and won*, and then collapsed on the ground.

At operation I found a piece of bone as big as a sixpence torn off with part of the origin of the sartorius muscle. I stitched it in place by sutures through the muscle and periosteum, with hip and knee flexed, and he has since won more hundred yard races.

Recently I have had another interesting avulsion, this time the lesser trochanter of the femur, in a boy of 12, who suffers from fragilitas ossium, with the usual accompaniment of blue sclerotics and an extensive family history of the same. This boy had had nine fractures previously, the last two years ago. With the idea of strengthening him his father put him under a "physical culturist," who succeeded in developing his muscles more than his bones, the result being a lesser trochanter torn off while running on level ground. It reunited quite readily under rest treatment with hip flexed and rotated outwards.—I am, etc.,

MAURICE G. PEARSON, M.B., B.Sc., F.R.C.S.

Durban, South Africa, July 15th.

GAS-OXYGEN ANAESTHESIA.

SIR,—I had not intended to join in the discussion initiated by Dr. Chambers, nor were the views in my article which was sent to him intended for publication in the *British Medical Journal*, but since he quotes from them I feel bound to reply briefly.

It is agreed by all that pure nitrous oxide-oxygen is the least toxic general anaesthetic at present known, although it has obvious limitations. The various machines designed for its administration all have their advantages and drawbacks. I, personally, have used Hewitt, Marshall, Boyle, Gwathmey, McKesson "G," McKesson "Special," and Walton types, and I have come to the conclusion that the skill and experience of the anaesthetist are of much greater importance than the machine he employs.

When giving gas mixtures by means other than face or nose inhalers, I definitely prefer the sight-feed type of apparatus. For example, the extremely useful rebreathing intubation method of pure N_2O-O_2 anaesthesia, introduced, I believe, by Drs. Magill and Rowbotham, and the endotracheal and endopharyngeal techniques using N_2O-O_2 with minimal ether, can all be done with the simplest machine.

With regard to teaching students, I believe that it is our duty to instruct men in the simple methods which will be most useful to them in after-life as general practitioners. If it is possible to include instruction in gas-oxygen anaesthesia during the very limited time available, surely it is better to teach them how to use a simple sight-feed apparatus, such as is to be found in most hospitals, than to explain the intricacies of some complicated imported machine costing nearly £100, and which the average practitioner would not dream of acquiring. If the student intends to take up anaesthetic work he will be well advised after qualification to apply for a post as resident anaesthetist at some large hospital, where he will have ample opportunity to obtain experience in every variety of anaesthetic procedure. He will then doubtless find out for himself the technique with which he gets the best results, and will eventually purchase the type of machine which fulfils his requirements. This is a purely individual matter, and there are probably no two anaesthetists who use exactly the same apparatus and technique, any more than there are two surgeons who do partial gastrectomies in exactly the same detailed way. Each man evolves the method which he finds gives him the best all-round results.—I am, etc.,

London, N.W.1, Aug. 10th. C. LANGTON HEWER.

SIR,—In recent correspondence on the subject of gas-oxygen anaesthesia Dr. Chambers quotes instances of writers stating that "they have had a bubble-bottle apparatus, and have not been able to do much with it," and at the same time he seems to dismiss rather lightly my point of contention, that to get good results from Boyle's apparatus "the greatest care must be taken in maintaining the perfect working order of apparatus." It is, in my opinion, principally because of neglect of this precaution that failures of accurate regulation of flow are recorded. Such failure is only attributable to one of three causes. First, the

delicacy of reducing valves is often ruined by the latter being used to shut off gas from cylinders when the apparatus is finished with, instead of using the "main tap." This procedure entails very tight screwing down of the reducing valves, which, after prolonged use of this variety, naturally fail to respond accurately to the hand of the anaesthetist when he wishes for one more or less "hole" of gas or oxygen. Secondly, unless great care is taken that the "sight-feed" bottle is not overfilled, drops of water tend to get blown over into the tubing, and this fact will almost invariably stem the regularity of flow of gases. Thirdly, the nitrous oxide may tend to freeze at the valve junctions. Using the non-freezing variety of nitrous oxide as now supplied by Messrs. Coxeters, this is now a very rare occurrence, and it can be still further guarded against by not opening the "main valve" of the cylinder too far at the commencement of use.

I am quite aware of the existence of other gas-oxygen machines, whose advocates claim finer degrees of control, but my argument was to the effect that gas-oxygen anaesthesia can be attained efficiently by means of a "bubble-bottle" apparatus, provided the above precautions are taken; that ether as an accessory anaesthetic is by no means always essential; and that, even in cases where ether is used, the amount is generally so small as to be for all practical purposes negligible.—I am, etc.,

London, Aug. 11th. T. de Lacy Walker.

*** This correspondence is now closed.—Ed., *B.M.J.*

THE NATIONAL MATERNITY SERVICE SCHEME.

Sir,—In the summary of the discussion on maternal mortality at the Section of Public Health in Manchester, published in the *Journal* of August 10th (p. 257), it is stated that I "spoke as the author of the scheme for an improved maternity service which had now become the policy of the Association." As this might be read to mean that I had claimed sole authorship of the scheme, may I be allowed to state that in the course of my remarks I merely said that I had had the privilege of sitting on the committee charged with the responsibility of preparing a scheme? The scheme was ultimately produced as the result of prolonged discussion, to which, of course, each member of the committee contributed his share.—I am, etc.,

Edinburgh, Aug. 10th. James Young.

PUERPERAL SEPSIS AND THE GENERAL PRACTITIONER.

Sir,—I was much interested to read Dr. Colin M. Craig's letter in your issue of June 8th (p. 1057), in which he tells of delivering cases with forceps in remote English farm-houses under hopeless conditions from the point of view of surgical asepsis. Having been a teacher of obstetrics and gynaecology I have had a varied experience of delivering women in villages in their own homes, with or without the aid of forceps or performing a craniotomy, and, to my consternation, many patients in whom I considered the prognosis perfectly hopeless made wonderful recoveries, even after previous meddlesome interference and unnecessary examination by what are called *dais* (women who attend confinements in a village, but have no knowledge of obstetrics or asepsis; this particular profession seems almost hereditary in India). Such good results often tempt one to disbelieve in that much belaboured "sepsis introduced from without," and to think that sepsis is for all practical purposes introduced from within—namely, teeth, tonsils, gall-bladder, bowel, etc. But there is no doubt—and here I disagree with Dr. Craig—that sepsis can be and is introduced from without. I have come across young, strong, healthy primiparae with no evident signs of infection of the teeth, tonsils, sinuses, etc., who, owing to bad (by which I mean septic) management by the village *dai*, have succumbed to a septicaemia. One of my patients who was lying on straw developed tetanus, which latter could not have been due to infection from within. The conclusion is that one must use all the precautions possible.—I am, etc.,

July 10th. A. F. Winnington da Costa, F.R.C.S.,
Civil Surgeon, Bilaspur, C.P.

FROZEN ORANGES.

Sir,—Considering all one hears about the importance of fresh food, it seems to me surprising that nobody appears to have noticed the great change in the condition of the orange as retailed in this country. Up to some years before the war one could be reasonably certain when purchasing an ordinary orange that a firm, full, juicy fruit would be obtained. Now such a fruit is almost unobtainable, unless an excessive price is paid for what is sold as a very special article. Indeed, those who wish for a fruit of the consistency of the former orange, and are not prepared for disappointment, are compelled to buy the more expensive grape fruit, which is still sold in the fresh state. The vast bulk of oranges when opened have a partially dried, fibrous appearance. The ends of the sections are dry, pale, and hard; the sections separate easily, and the separated surfaces have often a mouldy appearance, while, sometimes, the fruit appears to be definitely infected with mould.

I believe this changed condition of the orange is due to the fruit having been kept in cold storage in the hope of wringing some extra profit out of the consumer. In other words, instead of a living fruit we now get a frozen and dead orange, subject to altered conditions as regards evaporation and resistance to infection with moulds, etc. Oranges and apples probably form the chief or only fruit supply of the poor, while orange juice is the most frequently used source of anti-scorbutic vitamin for bottle-fed babies. Whatever may be the effect of freezing on the anti-scorbutic vitamin, I have seen from time to time sickness among babies attending infant clinics which, on investigation, seemed most likely to be due to the use of decayed oranges. Consequently I feel considerable difficulty in advising poor parents as to the use of fruit juice.

Seeing that the orange has been a common import for well over a century, and that for all, or the greater portion, of that period it has been sold, I presume profitably, as one of the cheapest of fruits, the preservation of oranges by freezing would seem to be an altogether unnecessary and retrograde measure calling surely for the serious attention of those whose duty it is to safeguard our food supply.—I am, etc.,

Swansea, July 30th. H. R. Tighe, F.R.C.S.I., D.P.H.

MEDICAL WOMEN AND THE BOARD OF CONTROL.

Sir,—In your issue of August 10th (p. 280) Dr. C. A. Mortlock-Brown writes of the "slight upon medical women" arising from the appointment of a new temporary medical man commissioner to the Board of Control. She appeals to the medical members of Parliament to rectify it.

It does not appear that Dr. Mortlock-Brown's objection to the appointment of Dr. Bedford Pierce lies in her knowledge of a medical woman better fitted than Dr. Bedford Pierce to fill the post, but that, because the patients are women as well as men, a medical woman of some sort should therefore be appointed. To what does this type of argument lead? Inasmuch as several women have been called to the Bar, and women not infrequently appear in the dock, it is obvious that women judges should be appointed without delay. Again, women travel by train, therefore women engine drivers should be added to our railway staffs. Conversely, as male as well as female infants are to be seen occupying perambulators, male "nursemen" must be found.

I venture to suggest that if Dr. Mortlock-Brown has no better reasons than those she adduces in her letter for the innovation she desires, she should spare herself the "wearisome and unpleasant job" of pushing the "rights" of her sex. I feel sure that few medical women will be grateful for her advocacy of their cause.

One still hopes and believes that appointments of this nature are made on qualifications for the post, and that the sex, religious opinions, political views, and other irrelevant matters do not weigh. When a medical woman arises who is better fitted to fill a vacancy on the Board of Control than any medical man, Dr. Mortlock-Brown need have little fear but that she will be appointed.—I am, etc.,

Cheltenham, Aug. 12th. John Bernard Davey, M.B.Lond.

Obituary.

EDWARD OCTAVIUS CROFT, M.D.,

Late Professor of Obstetrics, University of Leeds; Honorary Surgeon, Leeds Hospital for Women and Children and Leeds Maternity Hospital.

The death of Dr. E. O. Croft has come as a great shock and sorrow to a large circle of personal and professional friends. Though Dr. Croft had reached his seventieth year, his youthful figure and his alert manner made one forget his age, and so to many he appears to have died comparatively young. We are indebted to Professor T. Wardrop Griffith for the following memoir.

Edward Octavius Croft was the eighth son of Dr. Charles Ilderton Croft, who practised in London. He was educated at Epsom College, and until the end of his life took a

Dr. E. O. Croft.

(Photograph by James Bacon and Sons, Leeds.)

great interest in the school, of which he always spoke in terms of warm affection. His medical education was received at University College and Hospital, London; in 1883 he became M.R.C.S.Eng., taking the licentiateship of the Royal College of Physicians in the following year, and obtaining the M.D. at Durham in 1893.

After holding the appointments of resident obstetrical assistant at University College Hospital and resident medical officer to the General Lying-in Hospital, he came to Leeds in 1885. Until that year there was no special department for the diseases of women at the General Infirmary. These were supposed to be adequately dealt with at the Women and Children's Hospital, but the development of surgery and the increase in the number of patients led to the formation of a department for the diseases peculiar to women, with both an out-patient and an in-patient department. The first honorary medical officer in charge of this was the late Dr. James Braithwaite. Till this time the students had to rely upon the Poor Law officers and upon private practitioners for their experience in midwifery, and one of the great requirements which it was desired to meet, and one which the board of the infirmary was most anxious to co-operate in securing, was the establishment of an extern department for attending women in their confinements at their own homes. Fortunately for the Leeds School of Medicine, Croft was selected for the new post of resident obstetric officer. The writer of these lines, who was resident medical officer at the time of his election, can testify to the diligence, the tact, and the efficiency that he manifested in organizing the new department. Dr. Braithwaite was less interested in the midwifery side of his appointment than in that dealing with gynaecology, and the department of midwifery was practically launched by Croft. From this time the students have had every opportunity of gaining experience under adequate supervision in this most important part of their training; although, with the development of the new Maternity Hospital, with its in-patient department, the extern department of the infirmary has passed to the newer institution, the germ of Croft's early work in Leeds has blossomed in a way it could not have done had it not been well and wisely planted and nursed during its earlier years. Shortly after leaving the infirmary he was appointed to the honorary staff of the Women and Children's Hospital, and this position he held from 1890 till the time of his death.

Great though his contribution was to the teaching of midwifery, as has just been explained, everyone will feel that his chief reputation attaches to his association with this institution for which he worked so well, and for which he had such a deep affection. When the hospital was rebuilt he was concerned from the start with the work, watched with care every suggested improvement, and helped by his knowledge and acumen the completion of a building which is admirable in all respects. He was demonstrator and lecturer in obstetrics, and subsequently professor of obstetrics, in the University of Leeds. In his earlier years some general practice fell to his lot, but he relinquished this very soon, and confined himself to consulting work in obstetrics and gynaecology, in which he acquired a great reputation.

By everyone who knew him Croft was looked upon as a man of sterling integrity of character; quiet and reserved in manner, but with a charming laying aside of this when among those who were privileged to know him intimately, he was liked by all. His leisure time he devoted to natural history, and in his earlier years to long rambles in the country, which his residence in Yorkshire rendered so accessible. He served in the old Leeds Rifles for many years as medical officer, and made a regular appearance at the annual camp, where he was often the life and soul of the mess and a respected favourite with all.

The funeral service at Lawnswood was attended by a large number of his personal and professional friends, and the Women's Hospital was represented by Colonel Tetley, the chairman of the board of directors, and by others concerned in that institution.

ALEXANDER GORDON MILLER, M.D., F.R.C.S.Ed.,

Consulting Surgeon, Edinburgh Royal Infirmary.

We regret to record the death in Edinburgh, on July 29th, of Mr. A. G. Miller, who was one of those associated with Lister during his residence in that city.

Alexander Gordon Miller, who was born in 1843, was the son of James Miller, then professor of surgery in Edinburgh University, having succeeded Sir Charles Bell in 1842 when he was only 30. Alexander Miller was educated at Edinburgh Academy and graduated M.D.Ed. in 1864; three years later he became a Fellow of the Royal College of Surgeons of Edinburgh. In 1877 he was appointed junior assistant surgeon at the old Royal Infirmary, then situated in the High School Yards. In 1882 he became full surgeon at the new Royal Infirmary—the present building—and in 1897 he retired, after the full term of fifteen years' service, with the honorary title of consulting surgeon.

At the time when he joined the staff of the old Royal Infirmary as an assistant surgeon most of his seniors were general practitioners as well as surgeons; Mr. Miller combined both forms of practice for a short time, but then devoted himself entirely to surgery. When Lister went to Edinburgh in 1869 as professor of clinical surgery, Mr. Miller was one of those who accepted the new teaching with enthusiasm, though a certain amount of opposition was encountered from the senior surgeons of the Infirmary. He was a skilful and cautious surgeon, and a teacher who encouraged his students to practise careful investigation of all the cases they had to deal with. He took great interest in the welfare of the medical students, and was a keen supporter of the Royal Medical Society, and, at a later date, of the Students' Union. His method of amputation through the knee is well known, as also is his procedure

for reducing a dislocation of the shoulder by manipulation, while the bougie named after him is a most valuable instrument for dealing with a tight stricture.

In his younger days Mr. Miller was an excellent boxer and took keen interest in other forms of physical exercise. He was an enthusiastic walker, and knew the Pentlands well. When the wave of military enthusiasm spread over the country after the Crimea, he became a medical officer in the Queen's Edinburgh Volunteer Brigade, with Sir Douglas Maclagan and Dr. Patrick Heron Watson as colleagues. He was a staunch abstainer from alcohol, and did pioneer work in establishing the Medical Missionary Society, of which he held the post of vice-president for many years.

Dr. Hugh Campbell Highet, who died on July 29th at the age of 62, received his medical education at Glasgow and University College Hospital. He graduated M.B., C.M.Glas. in 1888, and proceeded M.D. in 1892; he obtained the D.P.H. of the Royal College of Physicians and Surgeons in 1901. After holding house appointments at the Glasgow Royal Infirmary and the Glasgow Eye Infirmary, he spent a year at the Hertford British Hospital in Paris. From 1892 to 1897 he engaged in private practice at Singapore, and was then appointed physician to the British Legation at Bangkok, Siam. He held this post until 1904, when he joined the Siamese service as principal medical officer of health at Bangkok; he was also ophthalmic surgeon to the Chulalongkorn Hospital, Bangkok. He was vice-president of the Far Eastern Association of Tropical Medicine and Hygiene, and president of the Siam Society. For his distinguished services in that country he was awarded the Order of the White Elephant. During the war Dr. Highet held a temporary commission in the Royal Army Medical Corps, and was appointed examining oculist to Winchester barracks. He subsequently returned to Siam for a short time, but in 1920 he went back to Winchester, where he practised as an ophthalmic surgeon, and was for some years honorary ophthalmic surgeon to the Basingstoke Cottage Hospital. He was a keen member of the British Medical Association, and in 1894, when honorary secretary of the Straits Medical Association, he took an active part in founding the Malaya Branch, which came into existence in the following year. He acted as honorary secretary of this Branch from 1894 to 1899. At Winchester he was for some time a member of the Southern Branch Council and its Executive Committee. Dr. Bruce Young, honorary secretary of the Winchester Division, writes: Dr. Highet's tact and *savoir faire* have been very helpful, but what perhaps more than anything else endeared him to us was his consistent geniality and friendliness, and his anxiety to help his fellows, both privately and in the life of the Division. These qualities, with his wide knowledge of the world and of men, combined to make him a colleague who was a high favourite with us all, and his sudden passing has been a cause of genuine grief to his many friends here. Just previous to his last illness he had willingly accepted nomination as chairman of the Division for 1929–30, but soon afterwards, in view of possible health developments, he reluctantly withdrew his nomination, much to our disappointment.

Dr. Stanley Bott, who died at his residence in Broadstairs on July 23rd, was born in 1879. He received his medical education at the London Hospital, where he obtained the diplomas M.R.C.S., L.R.C.P. in 1905; he graduated M.D. Durham in 1921. He held house appointments at the Westminster Hospital; the Royal Berkshire Hospital, Reading; and the County Hospital, Dorchester, and as a ship medical officer travelled frequently to the East and to Australia. He subsequently carried on practice at Caistor, Lincolnshire, in a scattered agricultural district, and during the war was involved in very heavy work, which eventually led to the breakdown in his health in 1923. For some time before his death he had lived in retirement at Broadstairs. He was the author of several articles in the *Lancet* on clinical subjects. He devoted himself almost entirely to his professional work, and was not greatly interested in anything else.

TESTIMONIAL TO SIR RONALD ROSS.

Fourth List of Contributors.

On May 11th we published a letter announcing that a fund, called the Ross Award Fund, was being started in order to give some recognition to Sir Ronald Ross for his discoveries on the mode by which malaria is carried, and for his lifelong efforts regarding the prevention of that disease. The letter stated that donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15, cheques to be crossed "Ross Award Fund a/c." The names of those who had contributed to the Fund up to May 17th were printed in our issue of June 8th (p. 1065); a second list of donors appeared on July 13th (p. 76); and a third list on July 20th (p. 129). We now print a further list of those whose donations, amounting to £652 7s., were received between July 1st and 12th. The total amount of the Fund on August 7th was £7,368 16s. 4d., which included £2,000 contributed by readers of the *Straits Times*, Singapore. The list published below does not include anonymous contributors or contributors whose initials only have been supplied.

Lord Aberconway, A. J. Avery.
Sir Harry Baldwin, J. E. Bracher, Miss E. C. Bell, B. Blackenson, Alan H. Black, D. Barnicott, Thomas Blakeley.
Miss H. Clarke, Miss E. M. Collis, Miss C. W. Cameron.
Mrs. A. H. Deane, Miss Nora Day, Duckwari Tea and Rubber Estates, Ltd.
Mrs. W. U. Gooding.
Dr. G. Hickes, Mrs. E. B. Holt.
F. J. Knight-Adkin.
Laras (Sumatra) Rubber Estates, Ltd.
J. M. Mackenzie, P. Monsley, B. Monsley.
Lieut.-Colonel H. R. Palmer.
Miss E. M. Read, Mrs. E. S. Rees, S. G. Rhodes, N. Raleigh, P. Raleigh.
H. E. G. Sobbé.
E. M. Vyvyan.
Dr. Watson-Griffiths, C. E. Wells, Miss M. A. Webster, Rev. and Mrs C. Kingsley Williams.

Universities and Colleges.

UNIVERSITY OF LONDON.

The annual report of the Graham Legacy Committee for the year 1928–29 records that Dr. G. R. Cameron has succeeded Mr. G. P. Wright as Graham scholar. The activities of the laboratories continue on the usual lines. Apart from the recipients of definite grants towards the expenses of their investigations, most of those engaged in research in University College Hospital Medical School were substantially assisted by the facilities and equipment provided by the fund. Grants amounting to £110 were made to six workers who had been engaged in special inquiries. Professor Boycott, M.D., F.R.S., has been reappointed Director of Research for one year from September 1st, 1929.

The date for the written examination for the academic Diploma in Bacteriology has been fixed for the first Tuesday and Wednesday in July, and the practical examination will commence on the Monday in the following week.

The regulations for the M.D. examination, Branch III (Psychological Medicine) have been amended by the addition after the words "A clinical examination" (Red Book, 1928–29, p. 247, and Blue Book, September, 1928, p. 234) of the words "in both mental diseases and mental deficiency."

Applications for the William Julius Mickle Fellowship, of the value of £200, must be received by the Principal of the University by, at latest, the first post on October 1st. It is awarded by the Senate annually to the man or woman who, being resident in London and a graduate of the University, has, in its opinion, done most to advance medical art or science within the preceding five years, and has shown conspicuous merit.

The Services.

GREENWICH HOSPITAL PENSION.

A Greenwich Hospital pension of £50 a year has been awarded to Surgeon Captain J. Andrews, R.N. (ret.).

DEATHS IN THE SERVICES.

Surgeon Major George Henderson, Bengal Medical Service (ret.), died at Inverness on June 23rd, at the great age of 92. He was born on November 29th, 1836, the son of the Rev. George Henderson of Cullen, and was educated at King's College, Aberdeen, where he graduated as M.D. in 1858, also taking the L.R.C.S.Ed. in the same year. Entering the I.M.S. as assistant surgeon on July 27th, 1859, he became surgeon after twelve years' service, and surgeon major on July 1st, 1873, retiring on November 20th, 1889, with over thirty years' service. Most of his service was in civil employment in the Punjab. He had a considerable reputation as a botanist, and for some time filled the post of director of the Royal Botanical Gardens at Calcutta, and afterwards that of professor of

medicine in the Lahore Medical College. He was the author of a *Catalogue of Plants in the Royal Botanic Gardens, Calcutta* (1873), and in the same year, in collaboration with A. O. Hume, I.C.S., of a work called *Lahore to Yarkand*, an account of a journey of exploration in Central Asia which they had together made. Henderson was the last survivor, in Bengal, of the Company's medical officers; there is one left in Madras, who now stands alone, as there is none in Bombay. He leaves a widow, two sons, and two daughters.

Medical News.

THE Fellowship of Medicine states that there is still one week remaining of each of the courses in urology at the All Saints' Hospital and at the Queen's Hospital for Children respectively. The former is an afternoon and evening course, and the latter covers the whole day; proportionate fees are payable. Special courses in the following subjects will be given during September: diseases of the chest, Brompton Hospital, September 9th to 14th; diseases of infants, The Infants Hospital, September 9th to 22nd; psychological medicine, the Bethlem Royal Hospital, Tuesday and Saturday mornings from September 10th to October 5th; medicine, surgery, and the specialties at the Westminster Hospital (for men graduates only), September 16th to 28th. A whole-day course in gastro-enterology will be held at the Prince of Wales's Hospital, Tottenham, from September 30th to October 4th. The Metropolitan Hospital will conduct its first all-day course, under the auspices of the Fellowship, in medicine, surgery, and the specialties, from October 21st to November 2nd. The Fellowship proposes also to hold another evening course for the M.R.C.P. examination, from October 15th to December 6th; it will consist of sixteen lectures by well-known authorities, on Tuesdays and Fridays, at 8.30 p.m., at the Medical Society of London, 11, Chandos Street, Cavendish Square. Full particulars of all these courses, information regarding the general course arranged by the Fellowship, and copies of its *Journal* are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE course on diseases of the nervous system will be held at the National Hospital, Queen Square, London, from October 7th to November 29th. The fee for the general course will be £6 6s.; it will consist of thirty-two clinical lectures and demonstrations, teaching in the out-patient department, and eight pathological lectures and demonstrations. It is also proposed to arrange for a course of eight lectures on the anatomy and physiology of the nervous system if there are sufficient applicants, and for a course of twelve clinical demonstrations chiefly on methods of examination of the nervous system. Full particulars can be obtained from the Secretary, Medical School, National Hospital, Queen Square, W.C.1.

A SERIES of lectures and demonstrations on the pathology of digestion, the radio-diagnosis of diseases of the digestive tract, and elementary laboratory methods will be held at the Hospital de la Santa Cruz y San Pablo, Barcelona, from October 5th to December 10th.

MR. L. S. AMERY, M.P., has accepted the chairmanship of the Imperial and International Committee of the British Social Hygiene Council. A diploma course in social hygiene has been instituted at the University of Aberystwyth, and steps have been taken by the council to secure the extension of instruction courses for Colonial officials before taking up appointments abroad. A joint committee of the British Social Hygiene Council and the board of study has been established for promoting the education of missionaries in this subject, with a view to equipping them with scientific knowledge.

DURING the Annual Meeting of the British Medical Association at Manchester a visit was paid to the school and working colony at Saddlebridge of the Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded. The party was shown round by Miss Mary Dendy, M.A., chairman of the society and founder of the colony. The colony consists of eight houses, workshops, a farm, a school, a recreation room, and a hospital. Suitable children from all parts of the country are received under the age of 13; they attend school until they are 16, and then pass on to the working colony, being, in most instances, then certified under the Board of Control. The men work in the gardens, on the farm, or in the various workshops as tailors, bootmakers, etc. The women undertake laundry work, sewing, knitting (by machine and hand), and some gardening. Those who visited it were much impressed by the efficiency and contentment of both children and adults, and by the exceptionally good health record.

DR. DUNCAN MACDIARMID, Oakbank, Kippen, and his wife, were, on August 2nd, the recipients of presentations from the people of Kippen, Fintry, and Gargunnock, on the occasion of Dr. MacDiarmid's retirement, after having been in practice in these districts for about forty years. The ceremony took place on the lawn at Oakbank House, in the presence of about 200 people. Mr. John Monteath of Wright Park, Kippen, presided, and the Rev. H. W. Hunter, Kippen, made the presentations. Among those who took part in the proceedings were Sir Steven Bilsland, Sir D. Y. Cameron, R.A., and Colonel Ewing Crawford of Duchray Castle, Aberfoyle.

TWO useful booklets have been published, one giving details of the "Harrogate cure," and the other describing the social amenities of the locality. Full information is provided with regard to clinical indications and the nature of the treatment, and both booklets are handsomely illustrated. They may be obtained without charge from the publicity manager, Mr. F. J. C. Broome, the Royal Baths and Wells, Harrogate. We have also received a booklet on similar lines dealing with Droitwich, and brought up to date for 1929. Application for it should be addressed to the manager of the baths, Droitwich Spa.

UNDER the will of the late Dame Edith Florence Waterhouse, wife of Sir Herbert F. Waterhouse, F.R.C.S., the Royal Medical Benevolent Fund Guild receives £500.

THE sixth Congress of French-speaking Paediatrists will be held in Paris, under the presidency of Dr. Barbier, from September 30th to October 2nd, when the following subjects will be discussed: oedema in infants, introduced by Dr. Cathala of Paris; rapid or unforeseen death in infants, especially during operations, introduced by Professors Nobécourt and Ombrédanne of Paris; jaundice in the newborn, introduced by Dr. Rocaz of Bordeaux. Further information can be obtained from the general secretary, Dr. Ribadeau-Dumas, 61, Rue de Ponthieu, Paris.

UGO BARBERI of Bologna has sent us a list of incunabula and other old medical books, as well as a list of five pictures of medical interest from one of the galleries at Bologna.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

VACCINATION AND ENCEPHALITIS.

"L. E. B." inquires: "Has there ever been known a case of encephalitis among non-vaccinated persons?"

*** An encephalitis, indistinguishable from that which occasionally follows recent vaccination ("post-vaccinal encephalitis"), quite commonly occurs idiopathically—that is, without being preceded by any known infectious disease: such an encephalitis also occurs after influenza and whooping-cough, again in subjects who have never been vaccinated or not vaccinated recently. In the *Lancet*, 1928, i, 1250, and 1929, i, 221, Russell Brain and Donald Hunter reported on six cases of encephalo-myelitis in children, three of whom were vaccinated

in infancy and two had never been vaccinated. (No reference to vaccination is made as regards the sixth child.) They distinguish this condition from encephalitis lethargica, but stress its marked clinical similarity with the encephalitis following vaccination. It is plain, therefore, that cases of encephalitis of the post-vaccinal type may occur in unvaccinated persons.

PRURITUS AFTER MUMPS.

CAPTAIN C. W. GREENWAY, R.A.M.C., asks for advice in treating a woman, who, after an attack of mumps of moderate severity, is now suffering from a generalized pruritus. He writes: There is no skin lesion, the condition being an intolerable itching over the whole body, which is worse at night. There is no obvious cause; the urine is alkaline, and there is no albumin or sugar present. *The patient is not, and has not been, jaundiced, and* feels in perfect health. My treatment has been: salines internally, bromides, alkaline baths, a calamine lotion containing *liquor carbonis detergens*, 4 drachms to the pint, and *liquor plumbi subacetatis*. The condition has improved somewhat, but only to relapse again.

TREATMENT OF SEVERE HEADACHE WITHOUT PHYSICAL SIGNS.

"M. B." asks for advice in the treatment of a woman, aged 35, who for several years has suffered from acute headaches chiefly during the menstrual periods. The headaches are usually frontal, sometimes unilateral, but sometimes vertical; they last three to four days, and are worse about the second or third day of the periods. They interfere with sleep and are not relieved by lying down. The patient is a multipara and is normal in all respects except for slight astigmatism; this has been corrected without any improvement in her condition. The bowels are regulated by aperients. The appendix has been removed, and also a number of suspicious teeth. All the usual remedies have been tried—phenazone, bromides, thyroid extract, calcium, etc.—but nothing seems to have the slightest effect.

"T. H. H." asks for suggestions for treating a woman, aged 60, who complains of severe attacks of headache and continued weakness, *but has no abnormal physical signs. The blood picture is normal,* as also is the non-protein nitrogen; the blood pressure is 110 mm. S.B.P., *and the urine is normal. The patient quickly becomes* breathless on exertion, but her cardio-vascular system appears healthy. Her climacteric occurred ten years ago. She is inclined to be neurotic, and has also had several attacks of dyspnoea which simulated asthma. She is able to walk about. Her eyes are normal. Her central nervous system shows no abnormal physical signs.

TREATMENT OF PLACENTA PRAEVIA.

DR. M. MALGLAVE (Dagenham) writes: With regard to the letter from Dr. D. C. Macdonald in the *Journal* of August 10th (p. 278), I should be very glad to know where "ovarian residue without corpus luteum" is obtainable; also if there is any known *physiology of its action.*

BLISTERING WITH SCARLET-RED.

"R. V." (Cochin State) writes: A patient with fistula-in-ano, operated upon a few days ago, was dressed with 1 per cent. scarlet-red ointment. About four hours later the dressings had to be removed as the patient was complaining of a severe burning *sensation. When the wound* was examined the whole surface, including the healthy parts with which the ointment was in contact, was found to be blistered. The wound was then dressed with boric ointment. Next day 5 per cent. scarlet-red ointment (Parke Davis and Co.) was tried. The patient was quite happy with it, and the wound is now showing signs of rapid healing. Can any reader suggest an explanation for the above?

TREATMENT OF LOCALIZED PULMONARY TUBERCULOSIS.

DR. J. B. DALÁL (Vejle-Fjord Sanatorium, Pr. Vejle, Denmark) writes: In reply to the query by "W. J. D." on July 27th (p. 171) as regards the treatment of localized pulmonary tuberculosis, I would suggest, in such a case, the performance of bilateral artificial pneumothorax, first on one side and then on the other.

INCOME TAX.

Succession—Cash Basis.

"A" and "B" were equal partners up to March 31st, 1928, when "A" retired. "B" bought "A's" share of the outstanding book debts for £350 and has included the cash received therefrom in his accounts for income tax purposes. Can he claim any adjustment, seeing that he paid for them out of capital?

*** The correct procedure would have been for "B" to calculate the profits of the practice for the year ended March 31st, 1929, as being the cash received *plus* any increase or less any decrease in the value of the book debts outstanding to the practice at that date as compared with March 31st, 1928. If that had been done no question as to the £350 paid by "B" would have arisen. But unless there has been some appreciable change in the volume of bookings the basis adopted will have produced a similar result, and with the advantage of a more convenient basis of calculation. If, however, "B" should find that the method actually followed has been averse to him, he should inform the inspector of taxes that he adopted the cash basis in error (it is not strictly applicable to the first year after a succession) and supply the figures calculated on the basis first mentioned above.

Car Transactions.

"R. M. L." bought a car in 1922 for £625 in respect of which he has received depreciation allowances amounting to £389, leaving a written-down value of £236. In April, 1928, he bought a second car for £158 and in June, 1928, he sold the first car for £57 and bought a third for £284. His accounts are always made up as at December 31st. What can he claim for 1929–30?

*** (*a*) Obsolescence allowance in respect of the first car—namely, £236 – £57 = £179. This amount is an expense of the year 1928, affecting, therefore, the gross amount of the assessment for 1929–30. (*b*) Depreciation allowance as follows:

Value brought forward			£236
Deduct: Sale	£57		
Obsolescence allowance	£179		
		£236	
			nil
Add: Second car			£158
Third car			£284
		£442	
Allowance at 20 per cent.			£88
Value to carry forward			£354

In his computation the inspector of taxes has not made the obsolescence allowance—presumably because it was not claimed—but has left the £179 in the calculation to increase future depreciation allowances.

LETTERS, NOTES, ETC.

A WARNING.

DR. J. G. BENNETT (Hyde, Cheshire) writes: May I caution *medical colleagues about a new type of confidence trick which* was played upon me to-day? It may help to save their pockets and also bring the perpetrator to book. While I was on my rounds a young man called at my surgery and intimated that he had come with a verbal message from me to the effect that my car had had *engine trouble and that it was being repaired on the* road. He then stated that I had sent him for 30*s.*, as I had no money with me, to remunerate the *mechanic who was on the* job at the time. My wife gave him the money, and obtained a receipt for it. When I returned home later the scheme was apparent, and on ringing up the police they informed me that they had had a similar complaint the same morning. Possibly the "receipt" may be useful later to establish identity—I sincerely hope so, for rogues of this kind seem to prosper.

DIET AND PRURITUS ANI.

"PANTAGRUEL" (Sussex) writes: I have recently had two separate experiences, each quite different from and independent of the other, yet I cannot help wondering whether they have any common factor. Perhaps someone more expert than myself in proctology and/or veterinary science can offer an opinion on this possibility. The first concerns a Sealyham terrier which gave obvious indications of pruritus ani, not amenable to anti-helminthic treatment, for some time before developing a rectal abscess, which necessitated a visit to a veterinary surgeon. This practitioner told me that in a state of nature and on a carnivorous diet a dog's motions are hard and are lubricated by *glands in the anus.* A diet consisting largely of dog biscuit, mainly farinaceous, results in soft motions, disuse of the rectal glands, loss of function, inflammation, pruritus, and frequently abscess. He stated that the condition was common among his canine patients. I was myself the subject of the second experience. I used to imagine that I could live more healthily and more cheaply on a diet containing a minimum of meat and other proteins and a maximum of farinaceous food. Judged by the action of my intestines (which we are frequently told is the great criterion of health), the results were very satisfactory. There were regularly from one to three copious soft formed motions a day. But I suffered considerably at times from pruritus ani, as well as being much troubled by a tendency to soil my linen, in spite of every precaution as regards cleanliness, such as using wet cotton-wool instead of paper. Rather more than a year ago, as a result of trying to get into a pair of trousers that had been made some years previously, I weighed myself for the first time for some years. I was horrified to find that, instead of about 11 st., as in the days of my athletic youth, I weighed over 12½ st. in middle age. I at once went on to a weight-reducing diet, a minimum of carbohydrates, with entirely satisfactory results, as indicated by the scales. It is well known that such a diet results in "constipation," but in my case I consider this word a misnomer. My motions continue to be from one to three daily, are ample in amount, and are passed without difficulty. But instead of being soft and only just formed, they consist of small hard masses. From being bovine in nature, they have become caprine. And, moreover, I am now completely free from any pruritus ani or any tendency to soiling of linen.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 40, 41, and 42 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 124.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

135. Fulminating Meningococcal Septicaemia.

THE lymphatics were formerly considered as the most frequent route by which meningococci reached the central nervous system, but of late years it has been recognized that meningococcaemia very frequently occurs before localization of the infection. Fulminating infections with this organism may occur and cause death within a few hours, the only clinical and anatomical findings being those of an intense septicaemia, and R. MIDDLETON and W. DUANE, jun. (*Amer. Journ. Med. Sci.*, May, 1929, p. 648), report an illustration of such an event. Two forms of purely septic meningococcus infection are defined. In the first there is a prolonged febrile state, characterized frequently by arthritic symptoms and a mild roseolar or petechial eruption. Prostration is often not severe, and this form may resemble typhoid fever or malaria. The second form includes fulminating cases with widespread purpuric blotches; in these patients death may occur very rapidly, and it has been reported as early as four hours after the onset of symptoms. In the authors' case death ensued in fifteen and a half hours; a remarkable feature was the intensity of the septicaemia, large numbers of meningococci being found in the blood smears. A strikingly low blood sugar value and marked hypotension seem to have been due to a bilateral haemorrhagic destruction of the suprarenal glands which was discovered at the necropsy. The total absence of suprarenal secretion, with the resulting failure of carbohydrate mobilization and vasomotor control, may well have been the immediate cause of death. The authors believe that meningococcal meningitis is frequently, perhaps usually, preceded by meningococcal bacteriaemia, and that vigorous intravenous therapy should never be omitted in such cases even when localization of the infection in the meninges seems to have occurred.

136. Adiposity following Suppression of Catamenia.

A CASE presenting the syndrome of familial adiposity with amenorrhoea and the unexpected effect of an injection of T.A.B. vaccine is reported by J. TROISIER and M. MONNEROT-DUMAINE (*Bull. et Mem. Soc. Méd. des Hôp. de Paris*, May, 1929, p. 546). A woman, aged 29, was admitted to hospital with influenza, and was found to be suffering from a syndrome due to endocrine disturbances. The menstrual periods had been regular in rhythm and duration from the age of 10 to 21, when the patient's weight was just over 8 st. At 21 menstruation abruptly ceased during a painful period, and the patient became pregnant in the course of the following month. Her general health remained good during pregnancy, but she became thinner and was unusually somnolent; 265 days after conception she had a difficult labour and gave birth to a child nearly double the normal weight. After the confinement there was complete cessation of the menses for nine years and a remarkable gain in weight. In the first month 15 lb. were added to her weight; and at the end of one year she weighed 19 st. She suffered from insomnia, and did not respond to hypnotics; oliguria was present. Succeeding years brought no alteration in her condition. Nine years after her confinement she had a subcutaneous injection of T.A.B. (Pasteur). After three days she had a progressive fever which persisted for three weeks with irregular oscillations, violent headache, and prostration. On the third day of this pyrexia menstruation started, was abundant, and lasted five days. After her recovery and discharge the menses continued as regularly as before her confinement nine years previously; moreover, she began to lose weight. During the vaccinial malady she lost more than 2 st., and afterwards in ten months she lost one-third of her weight without any dieting. Her general health apart from the influenza was perfect. Adiposity was still marked and oliguria present. The blood sugar figure was about 0.2 per cent., and the Wassermann reaction was negative. The sella turcica was normal, and the parasympathetic system could not be excited nor paralysed. Examination of the family history revealed the fact that the patient's mother and two sisters suffered from adiposity and amenorrhoea; one sister had given birth to an unusually large child. The patient's brothers were thin. The authors suggest that the inherited condition was due to a dissociation of female hormones. Presumably "hysterauxin" (the growth hormone of Champy) was circulating in the blood uncorrected by the "hysterythrin" (the congestive hormone of Champy); hence a condition of adiposity with amenorrhoea resulted.

137. Variations in Blood Pressure Produced by Meals.

SEVERAL investigators have recently emphasized the importance in diagnosis and prognosis of variations in blood pressure, and consider that too much stress should not be laid on the figures obtained from a single reading. Since, however, the observation of blood pressure at frequent intervals *over a comparatively prolonged period is often impracticable* clinically and "the response to effort" variations cannot be estimated in bed-ridden patients, H. MAY (*Med. Klinik*, May 24th, 1929, p. 829) has compared the alterations in blood pressure produced by a meal in healthy persons and patients suffering from various pathological conditions. For this purpose the systolic and diastolic pressures were recorded immediately before and during the meal and at intervals of five minutes for half an hour after. In persons with a normal circulation the alterations in pulse amplitude (difference between diastolic and systolic pressure) were similar to those produced by exercise, such as climbing stairs. The pulse amplitude was increased during the meal generally by 10 to 20 mm. of mercury; it fell to its initial value five minutes after the meal and then continued to diminish during the next half-hour, while in some cases this diminution was found to persist for one to two hours. In patients with circulatory failure the initial increase in pulse amplitude was small—up to 5 mm.—or absent, and in the more severe cases of failure was replaced by more or less prolonged diminution in pulse amplitude. In patients with chronic nephritis and high blood pressure the meal had no effect on the pulse amplitude. May therefore suggests that such blood pressure recording constitutes a useful and simple aid in estimating the efficiency of the circulation.

138. Rat-bite Fever.

F. C. KUIPERS and A. CHARLOTTE RUYS (*Nederl. Tijdschr. v. Geneesk.*, March 9th, 1929, p. 1207), who record an illustrative case in a boy aged 9, state that rat-bite fever may run its course without any local symptoms or eruption, fever being the only symptom. Mice inoculated with the patient's blood showed an infection with the *Spirillum morsus muriun*. The positive result was obtained by inoculating mice with the blood of patients on the day that the temperature fell after an attack. It is therefore advisable to inoculate mice with the blood of patients suspected to have rat-bite fever after the acme of the fever in order to obtain a positive result. The blood picture showed peculiar and constant changes. The most important was leucocytosis with relative lymphopenia and disappearance of the eosinophil cells during an attack, and an increase of the eosinophil cells some days before an attack. Eosinophilia was also found in convalescence. When rat-bite fever appeared to be cured *mild attacks might occur, manifested by rise in the pulse* frequently and the behaviour of the eosinophils and leucocytes. Salvarsan appeared to be of value therapeutically.

Surgery.

139. Ambulatory Operative Treatment of Haemorrhoids.

J. JENSEN (*Ugeskrift for Laeger*, May 16th, 1929, p. 419) has treated during the past eight years 413 patients with haemorrhoids (304 men and 109 women), of whom 199 (145 men and 54 women) required no surgical treatment, since conservative measures, such as special dieting, provided sufficient relief. The success of such conservative measures disproves the common belief that external haemorrhoids are necessarily an indication for some operation and a sojourn in hospital. Only internal haemorrhoids, and sometimes those of the intermediary group, under certain conditions, usually haemorrhage, require operative treatment, and then only after acute symptoms have disappeared. The author instructs patients to secure a thorough evacuation of the bowels before coming for operation; a modification of Whitehead's procedure is performed under local novocain-adrenaline anaesthesia after a hypodermic injection of morphine. The patient is subsequently taken to his home in an ambulance, and is visited the same afternoon or evening by a nurse, who gives an injection of morphine if necessary. The patient is also supplied with morphine drops. The nurse visits him twice a day, takes his temperature, and changes the dressings. Evacuation of the bowels is effected on the fourth day, and the patient is subsequently allowed to get up. After eight days he reports, and in many cases is fit for work in a fortnight. Among the 214 patients (159 men,

55 women) thus treated there were no fatalities or serious complications such as phlebitis, thrombosis, embolism, phlegmon, or abscess formation. Great care was taken at the time of operation to reduce the risk of post-operative haemorrhage, and only in three cases were patients admitted to hospital for this sequel; in two of these the haemorrhage was not serious, and the patients were discharged in a day or two. In the third case a rather severe haemorrhage occurred on the seventeenth day after the operation, the patient being 70 years old and suffering from arterio-sclerosis. On the rare occasions when retention of urine occurred the patient was catheterized at home by his doctor or taken to hospital, one or two catheterizations being usually sufficient to cure this condition. Among the 152 patients subsequently examined not one relapse had occurred; there was no troublesome stricture, and, even when cicatricial tissue could be felt, there was no obstruction to the passage of faeces. In every instance there was complete continence of normal motions, but in ten cases there were, under certain conditions, difficulties with regard to retention of flatus, which had in two cases existed before the operation. The author argues that the injection treatment of haemorrhoids cannot become the chief or normal treatment for haemorrhoids since it is not applicable to every case, it is uncertain in its effects, it provokes as many or more complications, and does not yield such good and permanent results as Whitehead's operation. On account of these drawbacks and the comparatively great number of cases of embolism and necrosis, the author believes that the injection treatment has been extensively abandoned.

140. Rupture of the Liver.

P. H. T. THORLAKSON and A. W. S. HAY (*Canadian Med. Assoc. Journ.*, June, 1929, p. 593) state that rupture of the liver, though rare, is an emergency quite amenable to early surgical treatment; they emphasize the importance of early diagnosis and prompt surgical measures. Owing to its size, consistency, and position the liver is particularly vulnerable to external forces, and the fact that lacerations usually occur along the posterior surface where the organ lies in contact with the vertebral column indicates that antero-posterior compression is the commonest cause of the injury. Eleven cases of rupture of the liver are reported; the mortality was 37.5 per cent., this high rate being chiefly due to the multiplicity of injuries and to the length of time between the injury and operation. The chief symptoms of ruptured liver are due to free haemorrhage into the peritoneal cavity. The patient becomes pale, weak, and later restless and dyspnoeic. The pulse becomes more frequent and compressible, and the blood pressure falls. Severe pain in the right upper abdomen, tenderness, and muscular rigidity are invariably present. The temperature is subnormal for the first few hours, and then gradually rises if the patient reacts favourably. Blood examinations at intervals show a progressive decline in the red cells and haemoglobin, but an increase in the leucocytes. Rupture of the liver must be distinguished from conditions of shock alone, and rupture of the stomach, kidney, spleen, or bladder. The primary shock should be treated for several hours, especially if the injuries are severe, and surgical measures should only be applied when this is past. If conditions indicate a decided loss of blood, a blood transfusion may be advisable just before or during the operation. As regards the operative site, the upper right transverse incision has certain definite advantages over the longitudinal one. Haemorrhage may be controlled by compression of the vessels in front of the foramen of Winslow, packing, tying, or by cauterization. Repeated observation of the following points is of great aid in determining the optimum time for operation: pulse rate and temperature; blood pressure; the numbers of red and white blood cells, and the haemoglobin percentage. The presence of other complicating injuries chiefly determines the prognosis. The authors stress the value of routine complete blood counts in all cases of severe injury, since these may later be valuable guides to the differential diagnosis and treatment.

141. Acute Osteomyelitis of the Pubis.

A. ZAFFAGNINI (*La Chir. degli Organi di Movimento*, April, 1929, p. 333) has collected 29 cases of this very rare disease. In a record of 1,469 cases of osteomyelitis only 23 were referred to the pelvis and none to the pubis. Of 71 cases of pelvic osteomyelitis collected by Klemm, 7 were pubic, 46 in the ileum, 16 in the sacrum, and 2 in the ischium. Zaffagnini met with only two pubic cases in hospital during eight years. Osteomyelitis, which has been described as "furuncle of bone," is an infective disease more commonly of the long bones, the site of attack being the growing tissue of the epiphyseal area, which has an increased capillary network and supply of blood, associated with a lowered resistance to infection. The commonest infecting organism is *Staphylococcus pyogenes aureus*, but *Staphylococcus albus*, a streptococcus, or any pyogenic organism of requisite virulence may be the causative agent, which is carried by the blood stream from the various sites of entry—skin, throat, tonsil, alimentary canal, and respiratory passages—to the medullary cavities of the long bones. It occurs in children of the school age; of 100 patients 41 were between the ages of 10 and 15. The frequent traumata among children favour the infection either by the direct admission of germs, or indirectly by extravasations of blood, which assist the attachment and development of organisms. Dislocation of an epiphysis seems especially favourable. The relatively high development of the lymphatic system in children, and the facility with which children catch cold, are contributing causes. The cases reported occur five times more frequently in boys than in girls. The disease is usually unilateral and slightly more frequent on the left side; one bilateral case is reported. In diagnosis radiography may reveal no changes, though *sometimes there is an increased transparency of the bone*; definite appearances are seen only after the destructive processes have commenced. The treatment is surgical and vaccine therapy is not advocated.

Therapeutics.

142. Calcium in the Treatment of Tuberculosis.

J. F. HALLS DALLY (*Brit. Journ. Tuberculosis*, April, 1929, p. 70) discusses the part played by calcium in the prevention and treatment of tuberculosis, and mentions that milk contains 0.72 gram in a pint, while half an ounce of cheese contains 0.14 gram. For administration he thinks the most useful form is a mixture of calcium carbonate and tribasic calcium orthophosphate, with 2 per cent. magnesium phosphate in 0.1 gram tablets (tricalcine); it may be given also in the form of powder or cachets by the mouth three times daily with meals. He also commends calcium gluconate, of which one teaspoonful may be given by the mouth three times daily, one hour after meals; this salt may also be injected intramuscularly or intravenously, the dose being 10 c.cm. every two or three days except in the case of severe haemorrhage, when still larger doses may be given with safety. He has obtained good results also with the double salt of calcium and sodium lactate, and colloidal calcium. The author finds that with these preparations more useful results are usually obtainable than when the lactate is used alone. He adds that a useful method of giving calcium chloride is in 10-grain doses in a mixture combined with 10-minim doses of dilute phosphoric acid. The relative lack of success in the treatment of tuberculosis by calcium, as compared with that reported by French authorities, is, he thinks, mainly due to improper selection of cases, though possibly the comparative lack of sunlight may also have some influence. Fibro-calcareous cases of pulmonary tuberculosis do not need calcium therapy unless their resistance becomes impaired; they then benefit by the exhibition of calcium alone. The exudative type of phthisis, however, calls for the administration of calcium in combination with parathyroid extract and vitamin D.

143. Bismuth as a Diuretic.

P. J. HANSLIK, A. L. BLOOMFIELD, A. B. STOCKTON, and D. A. WOOD (*Journ. Amer. Med. Assoc.*, April 27th, 1929, p. 1413) remark that although the diuretic action of the bismuth ion is prompt and definite when injected in the form of insoluble compounds or of soluble compounds in oil, its action does not usually last more than twenty-four hours; it is therefore of little value in cases where a sustained diuretic action is desired, as in conditions accompanied by anasarca or oedema. They thought that prolongation of its action might occur if water-soluble solutions were prepared, owing to the consequent more rapid diffusion and absorption of bismuth, and to the obviation of encapsulation. The excretion of the bismuth might also be completed sooner, thereby avoiding unnecessary actions of the bismuth on the body. Water-soluble bismuth sodium tartrate was accordingly tried on two convalescent patients without anasarca and oedema, and on three patients in which these conditions were present. This salt, said to be a tetrabismuth tartrate, is dispensed as a water-clear solution of 1.5 per cent. strength in a 25 per cent. (hypertonic) solution of sucrose containing 2 per cent. benzyl alcohol; 2 c.cm., or 0.03 gram, of the compound was injected intramuscularly as a single dose, or the equivalent of 0.0221 gram of metallic mercury. The patients also received constant supply of fluid throughout. The bismuth sodium tartrate injections were painless; they caused a prompt and well-sustained diuresis in subjects both with and without oedema. This action, which continued far longer than that observed with insoluble and oil-suspended bismuth preparations, was not accompanied by demonstrable

local or systemic reactions, and apparently did not injure the renal functional efficiency. The authors conclude, therefore, that it does not seem to be contraindicated in oedema associated with mild or moderate degrees of nephritis. The prompt, rapid, and complete excretion of bismuth after this compound is of practical importance in preventing possibilities of harm from retained bismuth.

145. Therapeutic Agents in Allergic Conditions.

A. H. W. CAULFEILD (*Canadian Med. Assoc. Journ.*, May, 1929, p. 493) reports the results obtained in certain allergic conditions by the use of trypsin and ephedrine, the latter being dissolved in gomenol. The work of Prausnitz and Kuster, and of Walzer, on allergy suggested the employment of large doses of trypsin or pepsin in cases of multiple food sensitization, in which food elimination, or desensitization, was difficult or impossible. Cases of bronchial asthma and urticaria occur in which food can be demonstrated or suspected to be a factor. Ephedrine ingested or applied locally in bronchial asthma and hay fever is highly regarded by authorities who have extensively tried it. Gomenol, an essential oil, is non-irritating to the mucous membranes, of pleasant odour, and has been much used for bronchial instillation. Bronchial instillations of solutions of ephedrine in gomenol were therefore tried in cases of bronchitic asthma—that is, in cases in which asthmatic spasms or respiratory distress occurred and were associated with a definite or presumable bronchitis. Frequent instillations were administered to 17 cases, and in only 2 was the treatment without a favourable effect; in 6 it was of considerable, and in 9 of pronounced, benefit. The favourable effect was prolonged from two to six days, and no case of idiosyncrasy to ephedrine was encountered. The method adopted was to instil into the trachea about 2 c.cm. of ephedrine (from 1 to 1.5 per cent.) in gomenol (10 to 20 per cent.) by the supraglottic method with a Yankhauer laryngeal syringe. The routine method when employing trypsin was to give daily three doses of 30 grains each for ten days, followed by an intermission. Four cases are briefly reported, illustrative of the benefits resulting from each method of treatment.

145. Indications for Malariotherapy.

G. STÜMPKE (*Deut. med. Woch.*, May 24th, 1929, p. 865) urges that the utmost caution should be exercised in recommending malariotherapy, for the following reasons. In general paralysis the patients generally offer little resistance and are usually of advanced age, the mortality in cases so treated ranging from 18 to 27 per cent. Moreover, the question of infectivity should not be dismissed so light-heartedly as is generally done. The investigations of v. Mühlens, Yorke, and Wright contradict the view that inoculated malaria is not infectious. Lastly, the cutting short of inoculated malaria by the usual methods (quinine and salvarsan) is not always successful. Stümpke obtained the best results from malariotherapy in cerebro-spinal syphilis and general paralysis, in which repeated examination of the spinal fluid showed that a decided clinical improvement was accompanied by a more healthy condition of the spinal fluid. As regards tabes, Stümpke thinks it better to apply some other form of fever treatment, such as Dmelcos vaccine (the French vaccine against chancroid), and comes to the conclusion that malariotherapy should be reserved for cases of general paralysis, cerebro-spinal syphilis which is refractory clinically, and cases in which the changes in the cerebro-spinal fluid persist.

Ophthalmology.

146. Trichinosis with Exophthalmos.

B. W. KEY (*Amer. Journ. Ophthalmol.*, March, 1929, p. 178) reports a case of the association of trichinosis with exophthalmos. A man, aged 25, came for treatment of lacrymation, puffiness of the lids, and headache. On examination some oedema of the lids was detected, together with considerable chemosis of the conjunctiva, more marked in the right eye than in the left, and some proptosis of the right eye. It was at first thought that the condition was due to nasal sinusitis, but on general examination a marked eosinophilia (69 per cent.) was found. A small section of the left deltoid muscle was excised, and on examination of this the curled-up larval *Trichinella spiralis* was seen. The acute course of the disease lasted seventeen days, and during this time the visual acuity varied considerably, though at no time did examination of the fundus reveal anything abnormal except possibly slight congestion of the disc. Treatment consisted of calomel followed by magnesium sulphate every four days; thymol, 3 grains twice a day; tincture of digitalis, 10 minims three times daily; and neosalvarsan, 0.2 gram every three days, six doses being given in all. It was found that he had been eating raw ham for his dinner every day during the week preceding his illness. Key comments on the various clinical signs in this case, and suggests that there may have been retrobulbar involvement, possibly neuritis, and due to trichina toxins, or a heavy infection of the extrinsic ocular muscles.

147. Remote Results of Dacryocystorhinostomy.

J. BASZERRA (*La med. Ibera*, April 27th, 1929, p. 545) records his observations on 283 cases of dacryocystorhinostomy, which he has performed in the course of the last four years for the treatment of dacryocystitis. His results were as follows: complete success in 85–88 per cent., relief or partial cure in 8–10 per cent., and failure in 5–7 per cent. Although the immediate result was excellent in every case, in some instances there was a return of the symptoms after an interval ranging from forty-eight hours to a month after the operation. In view of the satisfactory results obtained Baszerra comes to the conclusion that extirpation of the lacrymal sac in dacryocystitis should only be performed when dacryocystorhinostomy is contraindicated, or in a patient who, owing to advanced age and persistence of epiphora, does not wish to submit to a prolonged operation.

148. Amaurosis in Epidemic Encephalitis.

I. J. SANDS (*Journ. Amer. Med. Assoc.*, April 13th, 1929, p. 1241), who records an illustrative case, states that papilloedema is not a common occurrence in epidemic encephalitis, though cases have been described by Buzzard, Spiller, Kennedy, Naccarati, and others. Sands himself has encountered nine other cases, in three of which the diagnosis of cerebral tumour was made. Optic atrophy secondary to optic neuritis and papilloedema in encephalitis has been reported by Grinker, Hart, and others. Sands's patient was a woman, aged 37, suffering from epidemic encephalitis, who developed bilateral amaurosis and was totally blind for twelve days. Gradual improvement followed the injection of foreign protein in the form of typhoid vaccine.

Obstetrics and Gynaecology.

149. Cancer of the Cervix Uteri.

H. B. WOOD (*Med. Journ. and Record*, May 1st, 1929, p. 515) gives a summarized study of the records of cases of cervical carcinoma which occurred in the State of Pennsylvania during the year 1927. He reports that malignancy of the cervix is markedly increasing, and that there is no reason to believe that this increase is due to better diagnosis. More women are being saved by operation than formerly, and, therefore, with the increase in deaths there must be an even greater increase in the number of cases. The ratio of cervical cancer to that of the fundus cannot be determined, since many death certificates give merely "cancer of the uterus" as the cause of death without specifying the site. Cervical cancer usually spreads by extension into the surrounding pelvic tissues, but metastases into the lungs, stomach, liver, or other parts have been reported. Apparently the menopause is not an important factor in the development of cancer, since it began before that period in one-third to one-half of the cases. Childbirth also is not necessarily a factor in its causation, and multiplicity of pregnancies had no influence. Chronic irritation, usually regarded as provocative of cancer, was not present in all the childless patients. The returns showed a great variation in the duration of the disease, this ranging from one month to five years. Only one-third of the women were operated on, and Wood considers that this indicates the necessity for more extended educational methods and an increase of clinics for free diagnosis. Earlier operations are necessary, and a greater use of biopsy examinations for diagnostic purposes is advocated.

150. Paget's Disease of the Vulva.

J. A. DRAKE and A. WHITFIELD (*Brit. Journ. Dermatol. and Syph.*, May, 1929, p. 177) record a case of Paget's disease of the vulva with histological details, and discuss the etiology of this rare form of new growth. They conclude that this condition should be considered as a very indolent form of carcinoma. In the case of their patient the disease originated in more than one spot; in some places heavily affected ducts were seen leading to normal sweat glands, while in others normal ducts were connected with grossly involved glands. In the epidermis the disease began in the basal layer, some individual cells becoming affected, but not sufficiently close together to prevent completely the degeneration of the overlying mucous layer. Invasion of the fibrous tissues occurred only downwards from the surface epidermis, as was shown by an extensive downgrowth between the papillae, and the

heavy barrier of lymphoid and plasma cells which developed as a defensive reaction. The affected hair follicles, sweat ducts, and sweat glands, where no bursting through had occurred, showed no surrounding reactive infiltration. The authors consider that the "Paget cells" are of autochthonous production, and, in the case of the sweat ducts and glands, maintain their original position. On the other hand, in the case of the constantly proliferating surface epidermis these cells are detached and carried up between the normal prickle cells until they eventually reach the horny layer. The authors' patient was aged 68; she had been twice married, but had had no pregnancies. The condition had gradually increased for eight years, and the affected parts were so extensive that excision was not considered practicable.

151. Radium Treatment of Non-malignant Uterine Haemorrhage.

J. R. LINTON, G. A. MARKS, and G. VAN S. SMITH (*Journ. Amer. Med. Assoc.*, March 23rd, 1929, p. 966) report the results of treating by radium a series of 250 cases of uterine bleeding not due to malignant disease. With the exception of forty-one cases in which fibroid tumours were definitely present, only one patient had any demonstrable pathological condition (idiopathic thrombopenic purpura) which might account for the haemorrhage. All the patients with fibroid growths were relieved by the end of two weeks. In the 209 remaining patients immediate relief within ten days was afforded to all, by curetting followed by the introduction into the uterus of screened radium, except to one who died the day after admission; there were, however, twelve cases of recurrence. The one patient with purpura haemorrhagica had three local radium applications and intensive ultra-violet ray treatment over the spleen; she is now apparently well, nine years after her first admission. The authors state that no abnormal menopausal symptoms can be unquestionably attributed to the use of radium. There was some indication that the possibility of subsequent pregnancies was reduced, but the evidence was uncertain. None of the patients in the series had malignant disease at the time of treatment, and only two are known to have developed carcinoma later.

152. F. A. CLELAND (*Amer. Journ. Obstet. and Gynecol.*, April, 1929, p. 502) states that in adolescence radium should not be used until all other measures have failed, when the dose should be small enough to preclude any possible injury to the ovary. Not more than 200 to 250 mg. hours should be used in the initial treatment. The use of radium is of distinct value in controlling the menorrhagia of the menopause, 800 to 1,000 mg. hours of intrauterine radium giving satisfactory results in more than 90 per cent. of patients treated. Radium is contraindicated when there is a history of pelvic infection even eight or ten years previously, or evidence of existing infection. Preliminary curetting for diagnostic purposes should be performed in practically all cases when the patient is more than 40 years old.

153. Treatment of Engorged Breasts.

LOCAL applications of camphor have been used for many years to relieve pain in the engorged breast, but little reference has been made to its general effect on the lactating breast. N. W. PHILPOTT (*Canadian Med. Assoc. Journ.*, May, 1929, p. 494) reports the results of its administration in 80 cases, which indicate a definite inhibiting action by this drug on the milk secretion. Intramuscular injections of camphor in oil were given in doses of 1½ grains. The first day two injections were given, and one daily on the following three days. Other forms of treatment were discarded, and, though occasionally a loose Indian binder was used to support pendulous breasts, no form of pressure binder was employed at any stage. Of the 80 cases, 68 showed beneficial results, and in only 12 was the action slight or absent. This appears to be the most effective form of treating breast engorgement, and is far simpler and less painful than applying tight binders, local applications of ice, or the administration of large doses of magnesium sulphate. Philpott also believes that the child should not be put to the breast for at least twenty-four hours after delivery, and that both mother and child benefit from waiting till the breasts show signs of filling. Rest is most essential to the mother; suction on an empty breast causes much irritation, which predisposes to cracked or fissured nipples; in multiparae the after-pains on the second and third days after delivery are not so troublesome when the child is not taking the breast. Infants progress very favourably on the later nursing, and, if 5 per cent. lactose is given at regular intervals, dehydration and the usual starvation temperature are prevented.

Pathology.

154. The Excretion of Lead.

SINCE evidence has been presented that measurable quantities of lead are excreted in the urine and faeces of patients with and without a history of industrial exposure to lead compounds, and since Leake has verified these findings so far as faecal excretion is concerned, R. A. KEHOE and F. THAMANN (*Journ. Amer. Med. Assoc.*, April 27th, 1929, p. 1418) considered that further investigation was necessary. Few industries exist in which some lead compound is not used; an examination, therefore, into the entire occupational history of a person might yield information pointing to exposure previously unrecognized. Lead is present in the dust of city streets and elsewhere on the earth's surface. It is found so commonly in the carcasses of experimental animals as to suggest that meat-producing animals similarly have lead in their tissues; and other foods, especially fruits, often contain small amounts of lead. The authors accordingly made extensive investigations, a large number of persons being placed in the following groups: those with no occupational exposure to lead; those with slight exposure; and those with a present exposure to recognized lead hazards. They report that they have demonstrated that lead is excreted in the urine and faeces of normal persons, quite apart from industrial exposure to lead compounds; in those thus exposed the amount of lead excreted is in proportion to the degree of exposure. It is generally believed that absorbed lead accumulates in the tissues and that it is stored in a comparatively inert form in the bones. Evidence has been obtained in the case of experimental animals that such stored lead is not inert, and that its excretion is more rapid than is ordinarily supposed. To determine whether a person has absorbed significant amounts of lead it is necessary to study the excreta under carefully controlled conditions, over a period of time sufficient to equalize the variability of the excretory rate. Certain factors, such as acute illnesses, the administration of medicaments which are believed to influence the excretion of lead, and dietary variations, may seriously affect the processes of excretion and hence give rise to misleading information.

155. The Swarming of Proteus Bacilli.

O. MOLTKE (*Centralbl. f. Bakt.*, April 25th, 1929, p. 399) has studied the swarming of *proteus* bacilli by Orskov's agar block method. During the formation of the primary colony the bacilli are of moderate size, but after seven or eight hours or so, as soon as swarming sets in, the bacilli elongate extensively, forming long curved filamentous rods, which are in continuous movement. Experiments suggested that the time of onset of the swarming was determined largely by the thickness of the inoculating; the greater the number of organisms collected on a given area, the sooner did swarming commence. The author therefore considers that swarming is due to overcrowding and failure of nutrition at the site of the parent colony. The phenomenon does not occur on a plate that has already been used once for the growth of *proteus* bacilli.

156. The Intestinal Flora after Gastro-enterostomy.

B. PORTIS (*Surg., Gynecol. and Obstet.*, April, 1929, p. 470), as the result of experiments on dogs, came to the following conclusions. The upper intestinal flora was markedly changed after subtotal gastrectomy, and gradually assumed the faecal character of the lower intestine. Gastro-enterostomy did not materially change the bacterial flora of the intestinal tract. Alteration in the intestinal flora after partial removal of the stomach was probably owing partly to the loss of the bactericidal activity of the stomach through the establishment of achlorhydria, partly to the more rapid emptying time of the stomach, and partly to the alkaline medium of the jejunum. The clinical deduction to be drawn is that although partial gastrectomy seems to be the best operation in certain cases of gastric and duodenal ulcer, a new factor is introduced with the faecal change of the upper intestinal flora. The results of this alteration will take many years to establish.

157. Irradiated Cholesterin in Experimental Rickets.

G. VITETTI (*La Pediatria*, April 1st, 1929, p. 359) has devised experiments to determine the effect of irradiated cholesterin in rickets artificially produced in rats. He finds that the lesions produced by deficiency diet are in no way modified by cholesterin, and that if pushed it has a deleterious effect on the bone medulla, increasing the fatty content. The only positive effect he observed was a slight increase in the blood phosphorus content.

Throughout the span

of allotted years — from infancy with restricted diet, through manhood with irregularity of habits, to old age with failing muscular strength and intestinal atony, constipation besets "all types and conditions of men."

The remedy lies not in the doubtful results of harsh cathartics, but in helping the colon back to normal activity.

AGAROL BRAND COMPOUND

The original agar-agar emulsion

is dependable, mild, non-irritating to the organs. It lubricates the intestinal tract, softens the impacted fæces, and reactivates the peristaltic force and action.

A liberal quantity of Agarol Brand Compound for trial sent without cost or obligation to physicians.

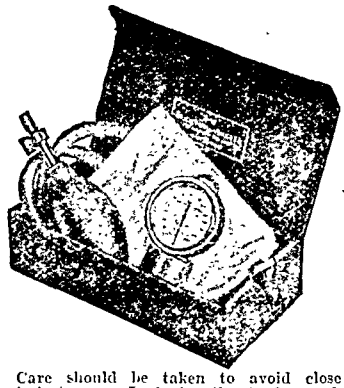
FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.



Care should be taken to avoid close imitations. Look for the trade mark 'TYCOS' engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

COLLENDER'S SPLINTS

(Patented in the Leading Countries of the World)

An evolution of the Thomas Splint—all the advantages of the Thomas Splint are preserved, with many important improvements, additions, and modifications.
They are supplied in strong fitted case, and enable 10 fractures simultaneously to be put up in any position obtainable by Thomas arm or leg Splints.
They provide the most modern methods of accurate extension, and safe transport of the patient is assured. Complete splints suited to limbs of any dimensions can be constructed in a few minutes from the component parts.

All members are interchangeable, standardised, numbered, and replaceable. They are made of Duralumin, which is untarnishable, exceedingly light in weight, and of great tensile strength. They can be immersed in sterilizing fluid without injury and can be used repeatedly.
Collender's Splints will be found invaluable for Hospital Emergency work and particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, an *to the Hospital from the farm, gardens, and orchards of Moulton* is a feature of this branch, and patients are given every facility in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56. Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE

(Associated with the General, Queen's, and Special Hospitals for Clinical Teaching.)

THE SESSION OPENS ON MONDAY, SEPTEMBER 30th, 1929.

The University grants Degrees in Medicine, Surgery, and Public Health, and a Diploma in Public Health; also Degrees and a Diploma in Dental Surgery.

The courses of instruction are also adapted to meet the requirements of other Universities and Licensing Bodies.

HOSPITAL APPOINTMENTS.

A large number of Resident Hospital appointments in Birmingham and District are open to qualified students of the School.

SCHOLARSHIPS, EXHIBITIONS, AND PRIZES.

Entrance and other Scholarships and Exhibitions and various Prizes and Medals are awarded annually in the Faculty of Medicine.

SCHOOL OF DENTISTRY. (University of Birmingham and Birmingham Dental Hospital.)

The School of Dentistry, in conjunction with the General and Queen's Hospitals, affords a complete curriculum for the Dental Diplomas and Dental Degrees of the University and all other Licensing Bodies. There is a Dental Scholarship of the value of £46 17s. 6d. offered annually.

PRE-MEDICAL AND PRE-DENTAL EXAMINATIONS.

The necessary Courses of Instruction in Chemistry and Physics and in Biology may be attended in the University.

RESIDENCE FOR UNDERGRADUATES AND OTHER STUDENTS.

There are Halls of Residence for Men and for Women Students. A register of approved lodgings is also kept by the Secretary of the University.

For Syllabus and further information apply to Prof. J. C. BRASH, M.A., M.D., Dean.

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION,

1, WIMPOLE STREET, LONDON, W.1. Telephone: Mayfair 2236.

POST-GRADUATE SPECIAL COURSES have been arranged for September and October as follows: Diseases of the Chest and Infants, Psychological Medicine, Gastro-enterology, and Medicine, Surgery and Specialities (Intensive Course), Cardiology, Ophthalmology, Tropical Medicine, Gynæcology, Diseases of Children and Throat, Nose, and Ear, and Medicine, Surgery and Specialities. Detailed syllabuses, "General Course" programme, from the Secretary.

UNIVERSITY OF LONDON. KING'S COLLEGE.

FACULTY OF MEDICAL SCIENCE.

COMPLETE COURSES OF STUDY ARE PROVIDED FOR THE PRELIMINARY AND INTERMEDIATE EXAMINATIONS OF:

(1) The University of London.
(2) The Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons; and also for
(3) The Degree in Dental Surgery (B.D.S.).
(4) The Primary Fellowship Examination of the Royal College of Surgeons.
(5) The First Professional Examination for the Licence in Dental Surgery of the Royal College of Surgeons.

The College, without in any way lengthening the duration of the Course, offers, like Oxford and Cambridge, the advantages of a broad University Education to Medical Students before they proceed with the purely clinical subjects.

Valuable Scholarships and Prizes are awarded on the results of examinations held annually.

The hostel for men students (King's College Hall, Champion Hill, S.E.5) is close to the hospital, and contains accommodation for 80 students. The hostel for women students is at 58, Queensborough Terrace, Bayswater.

For detailed prospectus of the Medical and Dental Courses and for further information apply to the Dean, Prof. R. J. S. McDOWALL, D.Sc., M.B., Ch.B., F.R.C.P.(Edin.), or to

S. T. SHOVELTON, M.A.,
Strand, W.C.2. Secretary.

Town Hall, Bradford. N. L. FLEMING, Town Clerk.

August 12th, 1929.

Woolwich Union.

THIRD ASSISTANT MEDICAL OFFICER (Male).

A *Third Assistant* Medical Officer (male) is required at the PLUMSTEAD AND DISTRICT HOSPITAL, Plumstead High Street, S.E.18.

Candidates must be single and be doubly qualified and registered.

The gentleman appointed must have held *Resident* Hospital appointments, and have experience in the administration of Anæsthetics. He will be required to carry out such duties as may be assigned to him by the Medical Superintendent, and should occasion arise, to assist at any of the other establishments under the control of the Guardians.

Salary £300 per annum, rising £25 annually to £350 per annum, with residence and rations, subject to deductions under the Poor Law Officers Superannuation Act.

Further particulars of the appointment may be obtained by personal application to the Medical Superintendent between the hours of 10 a.m. and 1 p.m. or by letter.

Applications, upon forms to be obtained at my office, as under, upon receipt of a stamped addressed foolscap envelope, or by personal application, must be returned to me not later than September 16th.

The appointment will be made by the Guardians at their meeting on October 3rd. The gentleman selected to appear before the Guardians will be notified, and if they have not had an interview with the Medical Superintendent they will be expected to call upon him before that date.

By Order,

Union Offices, Plumstead High St., S.E.18. ARTHUR HOLDER, Clerk to the Guardians.

August 12th, 1929.

Liverpool County Borough.

LOCAL EDUCATION AUTHORITY.

JUNIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited for a Junior Assistant School Medical Officer, in the Department of the Medical Officer to the Local Education Authority, at a salary of £600 per annum.

Applicants must be registered medical practitioners, and shall have had at least three years' experience. It is desirable that they should have had some special experience in school hygiene and in diseases of children.

The officer appointed will be required to devote his whole time to the service of the Education Authority, under the direction of the Medical Officer to the Education Authority. He will not be allowed to undertake private practice, and will be required to contribute to the Liverpool Corporation Superannuation Scheme, as required by the City Council.

Candidates must send in a statement of their qualifications, etc., to the City Council, and must obtain and forward to me not more than three recent *testimonials*, and endorsed "Junior Assistant School Medical Officer," must be delivered at the office of the Town Clerk, Municipal Buildings, Liverpool, on or before August 27th.

Canvassing of members of the Committee or the City Council is strictly prohibited, and will be considered a disqualification.

WALTER MOON, Municipal Buildings, Liverpool. Town Clerk and Clerk to the Local *Education Authority.*

July 20th, 1929.

Parish of Stepney.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Guardians invite applications from duly qualified medical practitioners for the vacant post of Resident Assistant Medical Officer at their Mile End Hospital, Bancroft Road, Mile End, London, E.1. Salary £450 per annum, together with full residential emoluments.

Candidates must have previously held a Resident House appointment at a Hospital, and the person appointed will be required to work generally under the direction of the Medical Superintendent.

The appointment is for a probationary period of six months in the first instance, and is subject to a medical examination as to physical fitness before commencing duties, and also to any provisions affecting officers in the Local Government Act, 1929.

Forms of application may be obtained from the undermentioned address upon receipt of a stamped addressed foolscap envelope or by personal application to the Medical Superintendent at the Hospital, and must be returned to this office by not later than Thursday, August 29th.

By Order,

Administrative Offices, Bancroft Road, Mile End, E.1. T. ROWLAND, Acting Clerk to the Guardians.

August 8th, 1929.

Kettering Urban District COUNCIL.

MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of Medical Officer of Health for the Urban District of Kettering.

Applicants must not exceed 45 years of age.

The gentleman appointed will be required to perform all the duties imposed on a Medical Officer of Health, to act as School Medical Officer, Medical Officer of the Joint Hospital Board, and to carry out all the duties in connection with the Council's Maternity and Child Welfare Service, and all such other duties as the Council, with the consent, if necessary, of the Minister of Health, may from time to time direct.

He will be required to devote his whole time to the duties of the offices and will not be permitted to engage in private practice.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926.

The successful candidate will be required to pass a medical examination.

The commencing salary, which will cover all the duties above mentioned, will be £825 per annum inclusive, rising by annual increments of £25 to a maximum of £900, subject to a rise or fall of 1½ per cent. for every five points variation in the cost of living, the salary being calculated on a basis of 65 per cent. above pre-war.

Applications, on forms to be obtained from me, together with copies of not more than three recent testimonials, must reach me not later than Monday, August 26th.

Canvassing in any form will disqualify.

Council Offices, High Street, Kettering. July 30th, 1929. JOHN CHASTON, Clerk of the Council.

City and County of Kingston-upon-Hull.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Corporation of Kingston-upon-Hull invite applications for the position of Medical Officer of Health of the City at a salary of £1,500 per annum, rising by annual increments of £50 to £1,750 per annum.

The gentleman appointed will be required to act as School Medical Officer for the City, and Port Medical Officer and Medical Inspector of Aliens for the Hull and Goole Port Sanitary Authority. He will be required to devote his whole time to the duties of the offices to which he is appointed and will not be allowed to engage in private practice, and all emoluments out of public moneys, which may be payable to or received by him, will have to be paid to the Corporation. He will be required to reside in the City and contribute to the Corporation's Superannuation Fund.

Particulars of duties and a form on which application should be made, may be obtained from the Town Clerk.

Applications, endorsed "Medical Officer of Health," addressed to the Town Clerk, Guildhall, Hull, must be delivered at the Town Clerk's Office, Hull, not later than September 7th.

HOUSE SURGEON.

The Committee require the services of a duly qualified Resident House Surgeon (male). Salary £130, with board, residence, and laundry. Duties to commence September 1st. Application, with copies of testimonials, to be sent to the undersigned.

LESLIE J. FURSLAND, Secretary.

Lowestoft and North Suffolk
HOSPITAL.

HOUSE SURGEON (male) required. Salary £150 per annum, with board, residence, and laundry. Applications, with copies of three recent testimonials, to the Honorary Medical Superintendent.

Coventry and Warwickshire HOSPITAL.

There being a vacancy on the staff for an HONORARY ANÆSTHETIST, applications are invited for the post.

Candidates must be duly qualified practitioners.

The appointment will be made for one year subject to reappointment annually.

Candidates shall be resident in the City of Coventry or within six miles radius thereof, or shall take up their residence within that radius within six months from date of appointment.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Application, with original testimonials and registration certificates, must reach the undersigned on or before August 31st.

Candidates will in due course receive notice of their eligibility or otherwise from the Secretary, and after receipt of such notice eligible candidates are at liberty to send through the post printed copies of their application and testimonials, to the Members of the Board of Management of the Hospital, a list of whose names and addresses will be furnished by the Secretary. No such application or copies of testimonials shall be sent until receipt of such notification from the Secretary.

By Order of the Committee,
(Miss) R. HOOPER,
Secretary.

August 15th, 1929.

Surrey County Sanatorium, MILFORD, SURREY. (300 Beds.)

Applications are invited from qualified and registered practitioners for the post of SECOND ASSISTANT MEDICAL OFFICER at this Sanatorium.

Salary at the rate of £400 per annum, plus board, lodging, and laundry, valued at £100 per annum for purposes of superannuation.

The appointment is subject to the Local Government and Other Officers Superannuation Act, 1922, and to the standing orders of the County Council.

Forms of application may be obtained from the Medical Superintendent, and when completed they should be sent to the County Medical Officer of Health, 5, Grove Crescent, Kingston-upon-Thames, not later than August 28th, together with copies of not more than three testimonials.

West Bromwich and District GENERAL HOSPITAL. (130 Beds.)

Applications are invited for the posts of
HOUSE SURGEON;
HOUSE PHYSICIAN;
CASUALTY HOUSE SURGEON.

Candidates (males) must be doubly qualified and unmarried. Salary, in each case, at the rate of £200 per annum, with board, residence, and laundry.

The appointments are for six months and the candidates will be required to take up their duties on October 1st next.

Applications, stating age and qualifications, with copies of three recent testimonials, should be sent to the undersigned on or before the 22nd instant.

By Order,
Edward St., West Bromwich. FRANK J. HANCOCK, Secretary & Supt.

Cardiff City Mental Hospital, WHITCHURCH, near CARDIFF.

RESIDENT CLINICAL ASSISTANT required for a period of six months, renewable for a second similar period. All found and an honorarium of 50 guineas for each period. The Hospital is recognized for Clinical Instruction for the M.D. Degree in Psychological Medicine, and the D.P.M. of the London University; and for the D.P.M. of the London Royal Colleges, and of the University of Cambridge. Ample facilities for ward and laboratory work. Facilities in general hospital work, by the courtesy of the honorary medical staff, Cardiff Royal Infirmary. Applicants should be qualified and registered medical practitioners.

Upon application to Dr. P. K. McCOWAN, Medical Superintendent, at the above address (from whom further particulars are obtainable), a form will be forwarded.

Cheadle Royal, Cheadle, CHESHIRE.

An ASSISTANT MEDICAL OFFICER (male) required in the above registered Hospital for Mental Diseases. Candidates must be unmarried, duly registered under the Medical Act, and not more than 30 years of age. Salary to commence at £350 per annum, with board, attendance, furnished apartments, and laundry. Facilities for attending classes for D.P.M. can be arranged.

Applications, accompanied by copies of three recent testimonials, to be sent to the Medical Superintendent.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (3 Lines)

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. WITHIN FIFTEEN MILES OF OXFORD. — Very old-established Country PRACTICE producing about £1,000 per annum, including about £550 from panel and appts. Patients comprise all classes. No resident opposition. Fees 2/6 to 10/6. Good house, with 2 reception, 4 bedrooms, separate entrance to professional rooms, etc. Nice garden, with tennis lawn. Rent on lease £70 p.a. Prem. £1,500.
2. HOME COUNTY.—Within 40 miles of London.—Good Country PRACTICE, established over 100 years, in very attractive district within 10 miles of favourite County Town. Patients include many county families. Income for immediate past year nearly £1,400, including transferable appts. worth about £120, and panel of 750, producing with mileage £470. Fees from 2/- to 21/-. Little midwifery. Excellent house, with 3 reception, 5 bedrooms, etc. Good garden. Garage. Rented on lease at £80 p.a. Premium £2,200.
3. HERTS.—PLEASANT TOWN within 40 miles of London.—PARTNERSHIP.—A one-third share (to commence with) in a very old-established sound middle-class Practice. Average income over £3,000, including panel of 1,800, and appts. worth about £300. Fees 2/6 to 15/-. Very good house, with large garden. Rent on lease £70 p.a. Sport of all kinds, and good schools. Premium 2 years' purchase.
4. PARTNERSHIP.—WITHIN 35 MILES OF LONDON, and within a few miles of the coast, a one-third share is for disposal in a very sound old-established Practice, producing last year over £3,600, and this year at the rate of over £4,000 p.a. Panel of 2,250. Fees 2/6 to 10/6. Good house, with 2 reception, 4 bedrooms, and professional rooms. Large garden. Garage. Premium £2,400, £1,800 down and balance by arrangement.
5. SOMERSET.—COUNTRY PRACTICE, within a few miles of the Coast. Old-established mixed general Practice, producing about £930 p.a., including panel and appts. worth nearly £600. Fees from 2/6 to 7/6. Good house, with separate entrance to professional rooms. Rent £58 p.a. Social facilities and schools. Premium £1,400.
6. YORKS.—LARGE TOWN.—Old-established mainly working-class PRACTICE. Income £1,250. Panel of over 1,400. Fees 2/6 to 5/-. Well-situated house, with good garden. Price £1,500. Prem. £1,800.
7. BORDERS OF WARWICK AND OXON. — Country PRACTICE in attractive district. Income nearly £1,200. Panel of nearly 600. Fees 2/6 to 10/6. Good house, with garden. Garage. Price for freehold £1,250. Premium 1½ years' purchase.
8. KENT COAST.—FAVOURITE RESORT.—Old-established non-panel, non-dispensing PRACTICE. Income £1,900. Fees 5/- to 10/6. Little midwifery. Large centrally situated house, with nice garden. Rent on lease £175. Good sport and schools, and social attractions. Premium 1½ years' purchase.
9. BORDERS OF CHESHIRE AND NORTH STAFFS.—Near large town. —Old-established good mixed PRACTICE. Income £1,100, including panel of 1,100. Good house on lease. Rent £52 p.a. Short but efficient introduction, as Vendor going abroad. Premium for quick sale £1,000.
10. BRISTOL.—PARTNERSHIP.—A half share in an old-estab. and increasing mixed general Practice. Income for last year about £2,050, including panel of 2,400. Fees 2/6 to 10/-. Low expenses. Good house, with nice garden. Electric light. Garage. Rent on lease £80 p.a. Premium £2,000.
11. NEAR EPPING FOREST.—Well-established and rapidly increasing mainly middle-class PRACTICE. Income for the present year at the rate of £1,200. Panel of 730, with good scope. Fees 3/-, 5/-, etc. Excellent house, not overlooked, with ample accommodation and good garden. Garage. Price for freehold, to include all fittings and fixtures, £2,500. Premium £1,800.
12. SUSSEX.—VILLAGE PRACTICE in delightful surroundings, at present producing over £1,150 p.a., but capable of considerable increase. Fees from 3/6 upwards. Exceptionally charming residence standing in 1½ acres of well laid out garden, and containing lounge hall, 2 reception, 7 bedrooms (3 fitted with h. and c. water basins), dressing room with fitted bath, and other usual offices. Central heating. Electric light. Garage for 2 or 3 cars. Premium £1,700.
13. HANTS.—COUNTRY PRACTICE, at present producing about £480 p.a., but offering large scope. Panel of 280. Fees 3/6 to 10/6. Mid. from 3 gns. Convenient house, with 2 reception, 5 bedrooms, etc. Garden and garage. Can be rented on lease at £75 p.a. Premium £800, part by arrangement.
14. LONDON, N.W.—Old-established mixed-class PRACTICE, averaging £2,000 p.a., including panel of about 1,500. Fees 2/6 to 10/6. Midwifery 3 to 15 gns. (about 50 cases yearly). Six-roomed house, with bathroom, kitchen, etc. Garage. Rent on lease £85 p.a.
15. PARTNERSHIP.—YORKS.—Suburb of large Town.—A share representing £750 p.a. (which will be guaranteed by Vendor for first 2 years) is offered in a well-established Practice producing about £3,000 p.a., offering large scope, and having a panel of over 2,000. Seven-roomed house available in nice district, with garden and garage. Can be rented; or bought for £750. Premium 2 years' purchase.
16. LIVERPOOL.—Centrally situated old-established PRACTICE. Income about £1,500. Panel of over 2,500, worked from Branch Surgery. Visits and medicine from 3/6 to 7/6. Little midwifery. Large corner house, with garden and garage. Recently redecorated. Electric light and new hot water system throughout. Price, freehold, £2,000. Large scope for increase. Premium 1½ years' purchase.
17. GLOS.—LARGE TOWN.—PARTNERSHIP.—A half share of an old established good-class non-dispensing Practice, owing to retirement through ill health of senior partner. Income about £5,000, with small select panel. Fees 5/- to 10/6. Purchaser should be about 40, married, and keen on midwifery. Good house available at low rental. Premium 2 years' purchase, part by instalments.
18. KENT.—FAVOURITE COAST [illegible]one-third share (to commence) in an [illegible]chiefly better-class Practice, averaging [illegible]£3,000 p.a. Fees 5/- to 21/-. Only about 10 midwiferies at from 3 to 10 gns. Very good house with 4 reception, 6 bedrooms, usual offices. Garden. Large garage. Price for freehold £3,000, half on mortgage. Premium 2 to 2½ years' purchase.
19. YORKS.—COAST TOWN.—Middle and working-class PRACTICE, averaging, for the last three years, over £1,800 p.a. Panel of 1,000. Fees 2/6 to 10/6. Little midwifery, but scope for this. Convenient house, with 2 reception, 5 bedrooms, etc. Small garden. Rent on lease £80 p.a. Premium 1½ years' purchase, £1,500 down and balance by instalments.
20. KENT.—COAST TOWN.—In a rapidly developing middle and working-class district, an increasing PRACTICE, producing this year at the rate of £900, including panel of 560. Fees from 5/-. Good freehold house, with large garden. Premium for Practice and house £2,000.
21. NEAR BATH.—Old-established unopposed Country PRACTICE, held by Vendor 10 years, and situated in an attractive district within easy reach of two good towns. Cash receipts for 1928 £656, and this year at rate of £700. Panel of over 500. Fees 2/6 to 12/6. Large house with 6 bedrooms, etc., and an acre of garden and paddock. Price for freehold £1,200. Premium £900.
22. CHANNEL ISLANDS.—Old-established better and middle-class PRACTICE. Income about £1,000, but has been much more. Fees 5/- to 21/-. Little midwifery. Large well-situated house freehold. Excellent schools and sport. Good hospital. Practice very easily worked. Price for house and Practice £4,000.
23. LIVERPOOL.—Mixed-class PRACTICE, producing this year at the rate of over £1,200. Panel of 560. Good house, specially built and well situated, containing 2 reception, 4 bedrooms, etc. Large garden. Garage. Price for leasehold £1,800, part on mortgage. Prem. £1,650.
24. MIDLANDS.—UNOPPOSED COUNTRY PRACTICE, near good town.—Well-established Practice, averaging over £1,000 p.a., including panel of nearly 600. Fees 2/6 to 10/-. Excellently situated house, with 2 reception, 5 bedrooms, etc., and separate entrance to professional rooms. Good garden and garage for 2 cars. Rent on lease £85 p.a. Premium £1,350.
25. PARTNERSHIP.—GOOD HOSPITAL TOWN in South-West of England. —A half share is for disposal in a good middle-class non-panel general and surgical Practice, averaging for the past three years over £5,000 p.a. Good house, with 2 reception, 6 bedrooms, etc. Premium 2 years' purchase. Purchaser should possess the F.R.C.S.
26. LONDON, S.W.—A one-third or half share in an old-established non-panel PRACTICE, situated within about three miles of Charing Cross. Receipts for last year nearly £2,300. Large scope. Fees 2/6 to 7/6. Not much midwifery. Good house, with garden. Rent on long lease £55 per annum. Premium 2 years' purchase.
27. SOUTH [illegible]N.—PARTNERSHIP.—A one-fifth share in [illegible]producing about £5,000 p.a., including [illegible]ry good house, with 2 reception, 5 bedrooms, etc., and usual offices. Rent on lease £45 p.a. Well-[illegible]ears' purchase.
28. [illegible] TOWN.—Well-established compact [illegible],600 p.a., including panel of 1,400. [illegible]idwifery. Low expenses. Very well-situated double-fronted house, 2 reception, 4 bedrooms, etc., and good professional rooms. Garden. Price for freehold £1,500 (£1,000 on mortgage). Premium 1½ years' purchase.
29. MANCHESTER.—PRACTICE is situated in a growing district offering very good scope. Income for the immediate past 12 months over £1,600, including panel of nearly 900. Fees 3/6 upwards. Detached well-situated house, with 3 reception, 5 bedrooms, etc. Can be rented on lease at £110 p.a. Premium 1½ years' purchase.
30. EASTERN COUNTIES. — Unopposed Country PRACTICE, easily worked, and situated in beautiful district, near two good towns. Average cash receipts for past three years £1,064, including panel of 530. Nice house, with 3 reception, 6 bedrooms, etc. Price for freehold £2,000. Premium £1,500.
31. WITHIN 50 MILES OF LONDON.—In a small Country Town, in pretty district, a well-established increasing PRACTICE, worth last year over £800, including panel of 525, and appts. about £60. Visits 3/6 to 21/-, medicine extra. Very good house (3 reception, 5 bedrooms, etc.), with large garden. Tennis court. Garage. Electric light. Price for freehold £3,100. Premium 1½ years' purchase. Exceptionally good educational facilities for boys.

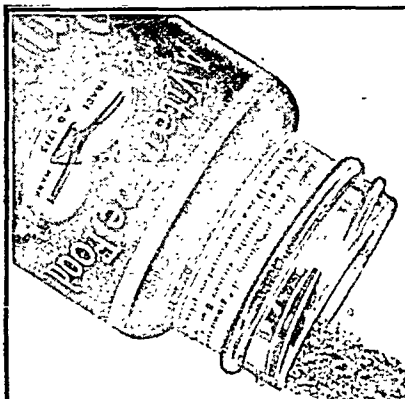
Details of the various Services and branches of specialist practice will also be included. The enlarged Advertisement Sections will contain much that is of value to the Student and Practitioner, and will certainly repay careful examination.

Announcement by the British Medical Association



The Pre-eminent Vitamin Food

"Bynotone"

"The vitamin problem is of far greater importance than is generally realised . . . . . The vitamin question should first be attended to in the bringing up of infants and young children."—PLIMMER.

"The results of prolonged minor degrees of vitamin deficiency give rise to inferiority in physical development, instability of the nervous system, lack of recuperative power and endurance, and consequent cumulative fatigue and lack of resistance to infection."
McCOLLUM & SIMMONDS.

"Bynotone" is a concentrated nutrient rich in the vitamins *A*, *B* and *D* and other elements which, though often deficient in the ordinary everyday dietary, are of vital importance to nutrition.

"Bynotone" contains essentially—bone marrow, yeast extract, hæmoglobin and liver fat; the latter is prepared by a special process and is the richest known source of vitamin *A*. The natural vitamin content of the ingredients of "Bynotone" is augmented by the addition of a proportion of synthetic vitamin *D*.

"Bynotone" is the ideal accessory food during the ages of active growth and adolescence, the periods of expectant and nursing motherhood and the stage of convalescence after acute disease.

It is a nutrient, hæmatinic and restorative which assists the assimilation of other foods and promotes general good health.

COAGULEN-CIBA IN HÆMORRHAGE

Five correspondents in *The British Medical Journal*, July 28th, 1928, p. 182, testify to the value of Coagulen-Ciba in Hæmophilia.

Reports on the successful administration of Coagulen-Ciba were published in *The Lancet*, October 31st, 1925, p. 918, Intestinal Hæmorrhage; *The Lancet*, June 13th, 1925, p. 1238, Hæmoptysis treated by Intrapulmonary Injections; *The Lancet*, January 24th, 1925, p. 176, Hæmorrhage following Tonsillectomy.

Three cases (two Hæmoptysis, one Bowel Hæmorrhage) successfully treated with Coagulen-Ciba by the mouth are reported in the *Journal of the Royal Naval Medical Service*, No. 1, Vol. XII, pp. 64-65.

Full particulars and reports to Physicians on request.

HYPERACIDITY

An Equilibrium is Maintained

CALSOMA (**"Abbott"**) is the rational remedy for hyperchlorhydria. It presents the tribasic phosphates of calcium and magnesium, sodium biphosphate and magnesium citrate in pleasant, palatable, effervescent form. A gastric antacid which neutralises excessive acidity *without producing alkalosis.* The administration of the usual alkalis, such as bicarbonate of soda, is unsatisfactory, for they produce systematic alkalinisation and throw stress upon the kidneys.

CALSOMA (**"Abbott"**) does not produce alkalosis. It gives prompt relief in acid indigestion and from the pain of gastric and duodenal ulcers. At all chemists on prescription.

FOR the guidance and assistance of those wishing to enter the Medical Profession, and for those already qualified who are desirous of planning a career, it has been decided to publish, on

August 31st,

a

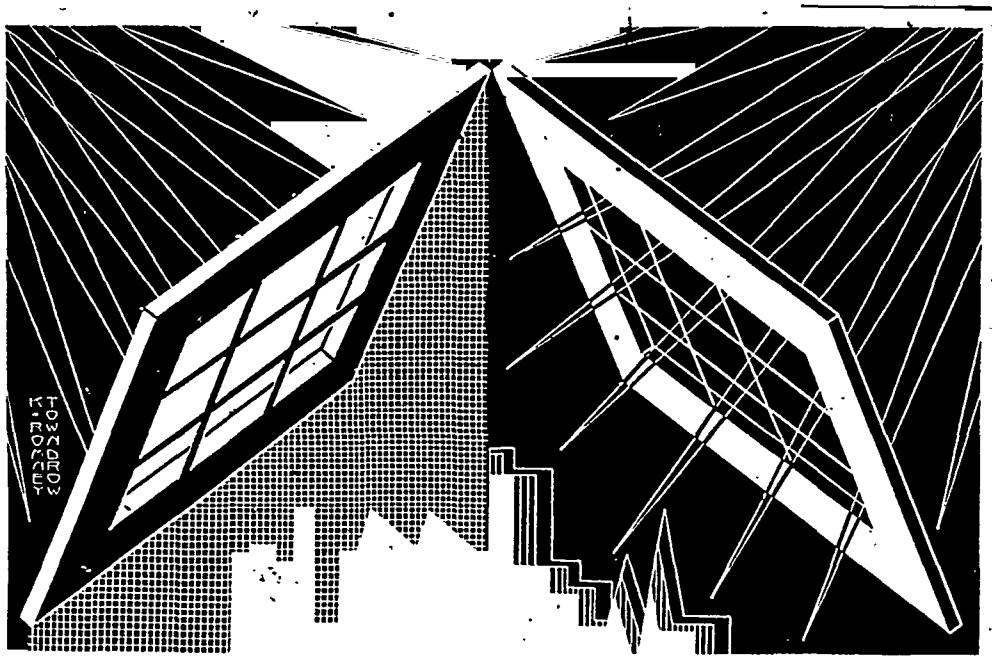
Special Educational Number

of the

British Medical Journal

THIS Number will contain full information regarding Medical Education and the fees charged by the teaching and examining bodies in England, Scotland, and Ireland. Details of the various Services and branches of specialist practice will also be included. The enlarged Advertisement Sections will contain much that is of value to the Student and Practitioner, and will certainly repay careful examination.

Announcement by the British Medical Association



HEALTHY HOUSES DESIGNED IN THE CONSULTING ROOM

Thousands of homes are influenced by what their owners learn in the doctor's consulting room. The doctor is the architect of health. His recommendation can transform a healthless room into a healthy room; and he effects such changes every time he suggests the use of "Vita" Glass to his patients.

"Vita" Glass is the only British window glass that admits the ultra-violet rays which ordinary glass shuts out. Its power of admitting these rays is permanent, and "Vita" Glass windows are effective health inlets all the year round, whether they face north, south, east or west.

"Fit 'Vita' Glass" is not a costly suggestion to-day. For a window of average size can be fitted with "Vita" Glass for 38/-, plus the cost of fixing.

Further information about "Vita" Glass will be sent to any Medical man who is interested. Write to: "VITA" GLASS MARKETING BOARD, 9 Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

health through your windows

"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

THE HOLBORN SURGICAL INSTRUMENT CO., LTD., 26, THAVIES INN, HOLBORN CIRCUS, E.C.1.

Specially indicated in

NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA

and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

Samples and Descriptive Literature from Sole Distributing Agents for U.K. and Irish Free State: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

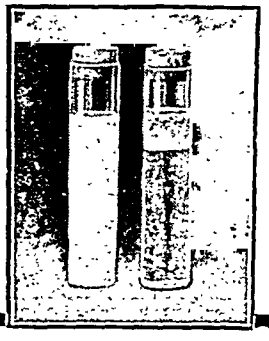
Action of Antiseptics on Organic Salts

Important Findings

The left hand test tube below shows Lysolat in a state of perfect emulsification in a 3% solution of Sodium Chloride whilst a well-known liquid Lysol (right hand test tube) has broken down under the same conditions.



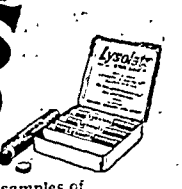
One of the problems of antiseptic practice has been the rapid deterioration of emulsified disinfectants on contact with organic matter. As doctors know only too well, the salts break up the emulsiou, throw out the active principle of the antiseptic, and destroy its bactericidal value.

Experiments with 10% solutions of many lysols and other disinfectants in wide use have revealed that Lysolat alone preserves a perfect emulsion in salt solutions and in sea water; in fact, a solution of 3% sodium chloride, or for that matter any chloride, would destroy any other cresylic acid preparation, whether proprietary or otherwise.

Surgeons will realise the significance of these tests, for obviously the physical action of the antiseptic in disintegrating dirt, grease, and blood clots, and attacking the bacteria within, remains unimpaired. Lysolat is specially sensitised with a protective colloid, which preserves its efficacy under the most difficult conditions encountered by the surgeon or the chemist.

Lysolats

PATENT 118667 (LYSOL TABLETS)



Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney St., London, S.E.1

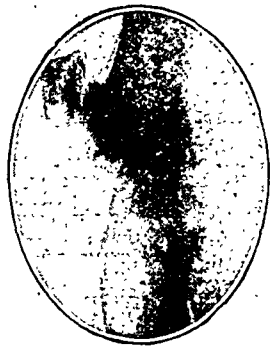
'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready Solubility in water. Well tolerated. Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Radiograph of Hip-joint in Rheumatoid Arthritis

BOOTS PRODUCTS

Insulin (BOOTS)

INSULIN (BOOTS) is prepared in the Nottingham Laboratories of Boots Pure Drug Company Ltd., under Licence No. 19 (Therapeutic Substances Act, 1925) of the Ministry of Health.

It is made from selected ox pancreas which is subject to the strictest examination before use.

The bulk Insulin is first tested for potency and sterility in the Company's own Pharmacological and Bacteriological Laboratories.

It is filled into ampoules and again tested for potency and sterility.

Every batch of Insulin (Boots) is submitted for further testing to the British Medical Research Council, and is passed by the Council before issue.

Insulin (Boots) is tested against the International Standard Insulin, in accordance with the provisions of the Therapeutic Substances Act.

The problem of

Maternal Mortality

It is now recognised that the maternal mortality rate is intimately associated with the incidence of puerperal septicæmia, and, in view of this, recent results (*B.M.J.*, June 1st, 1929, p. 984), disclosing the fact that puerperal sepsis may be cured simply by the administration of therapeutic doses of

RADIOSTOLEUM

have opened up "*a vista of rich promise*" to all who are concerned with the problem of maternal mortality.

Cremo - Carbonates

(Tri-Carb-Cream-Mulford)

Effective
Non-Caustic
Palatable

H. K. MULFORD
CO. LTD.,
Regent Arcade House,
252, Regent Street,
London, W.1.

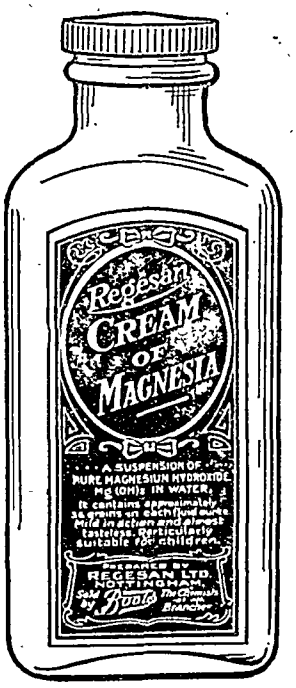
CREMO-CARBONATES presents certain unique features which warrant its preference whenever an antacid and corrective is indicated. For the first time the well-known protectives and antacids, bismuth, magnesia, and lime, are supplied as a suspension of particles of colloidal dimensions.

Its colloidal nature gives it maximum covering power superior to that of a mere mechanical mixture of bismuth, magnesium, and calcium.

CREMO-CARBONATES is a soothing, antacid corrective and digestant, particularly useful in the treatment of hyperacidity accompanied by flatulence and of any other conditions where there is excessive secretion of the gastric juices.

Literature and samples sent free to members of the medical profession.

HR



Regesan

CREAM OF MAGNESIA

A pure, finely divided Magnesium Hydroxide ($Mg(OH)_2$) suspended in water. A simple antacid and valuable laxative. Digestive troubles and gastric conditions indicating the necessity of a corrective of this type quickly respond to treatment with Regesan Cream of Magnesia.
It does not gripe nor cause discomfort, and is mild in action.

Price 1/3 per bottle.

Full size trial sample free (in the British Isles) on application by postcard to Boots The Chemists, Station Street, Nottingham.

OVALTINE

PHOSPHORUS IN NEURASTHENIA

Although it is realized that much difference of opinion prevails in medical circles as regards the therapeutic value of phosphorus, it is not illogical to claim that where the element is indicated, as in the neurasthenias, its tonic and restorative effects are more likely to be produced from natural phosphorus nutrients, such as those in "Ovaltine," than from medicinal products.

In the majority of cases in which "Ovaltine" has been prescribed for its "phosphorus" effect—that is, for its tonic and restorative effect upon the nervous system—the results of its administration have been gratifying in the extreme.

"Ovaltine" has been used with marked success in neurasthenia of the type known as cerebral neurasthenia, or psychasthenia, a variety of which is induced by excessive mental labour, or by worry, anxiety, or nervous strain.

The delicious flavour of "Ovaltine" renders the product acceptable even to the most fickle or jaded palate, while its exceptional nourishing qualities exert a profound influence for good health.

A liberal supply for clinical trial sent free on request.

Local Anæsthesia in Surgical Practice

REMOVAL OF GOITRE.

Typical Case.

C. C. H., male, aged 46 years.

Diagnosis: Toxic colloid goitre.

Operation: Partial Lobectomy.

Anæsthesia: Local infiltration and cervical block: 120 c.c. of a 0.5 per cent. Novocain-Adrenaline solution were used.

Operation: Classical subdermal infiltration and cervical block was made. 60 c.c. of a 0.5 per cent. Novocain-Adrenaline solution were introduced subdermally, and 30 c.c. were used on each side for blocking the cervical nerves. A large intrathoracic colloid goitre was removed from the left and a small adenoma from the right.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

for nervous & heart disorders, rheumatic conditions, etc., etc.

B

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat"

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

Cow & Gate Milk Food

PACKED IN A BLUE TIN

This food has the following composition:—

	Dry Food			Reconstituted (1 part in 8 parts of water)
Fat	15.5%	...	...	1.7%
Proteins	20.0%	...	...	2.2%
Lactose	58.0%	...	...	6.4%
Mineral Matter	4.5%	...	...	0.5%
Water	2.0%	...	...	89.2%
	100.0%			100.0%

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The manufacturers will gladly supply samples and any further information, if required, and wish to remind Members of the Medical Profession that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

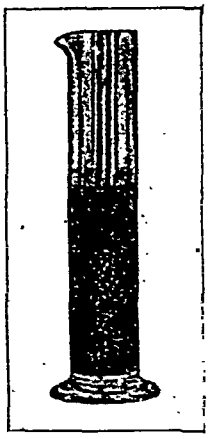
"Allenburys" The DIET

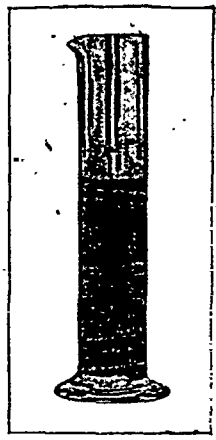
A Stimulating and Sustaining Food Beverage



A Showing the heavy curd formed by the action of gastric juice on ordinary cow's milk.

A solution to the problem of feeding in many acute and chronic affections is found in the use of the 'Allenburys' Diet, which presents distinct advantages over cow's milk both with regard to food value and digestibility. The 'Allenburys' Diet is a palatable and highly nutritive food beverage prepared from pure fresh full-cream milk and whole wheat, and is particularly easy of assimilation. It replaces with advantage milk and the milk dishes commonly employed in sickness and convalescence and can often be taken and retained where other foods are rejected. As a stimulating and sustaining beverage for people of all ages, it is infinitely superior to tea, coffee, etc. It can be made in a minute simply by adding either boiling water or milk.

In tins at 2/1, 4/- and 7/6.



B Showing the finely flocculent curd formed by the action of gastric juice on the 'Allenburys' Diet.

Descriptive Literature and free clinical sample will be gladly sent on request.

Remarks ON APICAL AND SUBAPICAL TUBERCULOSIS.*

BY

MAURICE FISHBERG, M.D.,

CHIEF OF THE TUBERCULOSIS SERVICE OF THE MONTEFIORE HOSPITAL; CONSULTING PHYSICIAN TO THE BEDFORD HILLS SANATORIUM, NEW YORK, U.S.A.

PATHOLOGIC anatomists and clinicians have known for many years that the number of people with tuberculous lesions in the lungs is much higher than that of those suffering and dying from actual tuberculous disease. Apical tuberculosis—active, quiescent, completely cicatrized, or calcified—is a banal incidental finding at necropsies of persons who have succumbed to any other disease, and who during life have either not known at all that they had lung trouble or considered their pulmonary symptoms of little if any significance. Of the 60 to 90 per cent. of tuberculous foci observed in routine necropsies, 30 to 60 per cent. are found to have been "obsolete." In other words, it appears that a large proportion of tuberculous lesions of the lungs heal spontaneously. This confirms the common observation of clinicians, who often find unequivocal symptoms and signs of apical lesions, yet the patients are getting along fairly well with or without treatment. These are facts known to all who have given this subject thoughtful attention in their routine work in sanatoriums, in dispensaries, and in private practice, and may be considered clinical platitudes.

Our great problem has been to differentiate these benign cases from the numerous others that are progressive and require treatment, be it climatic, institutional, or operative. Heretofore we held to the dictum—or should I say dogma?—that when there are changes in the resonance and breath sounds, perhaps also some adventitious sounds, over the region of the lung above the second or first rib, the patient is tuberculous; if there are also such constitutional symptoms as cough, loss of weight, fever, haemoptosis, etc., there is no doubt that there is an active lesion which must be cared for in accordance with the principles of modern phthisiotherapy. On the other hand, if the signs indicate a lesion lower than the apex, the chances of its being tuberculous are remote; at any rate, considerable circumspection must be exercised before pronouncing the patient tuberculous.

During the first years of wide application of the Roentgen rays in the diagnosis of pulmonary pathology these diagnostic principles appeared to have been confirmed. But with the more universal use of the Roentgen rays there has taken place during the past five years a radical change in our views of the early localization and evolution of tuberculous lesions in the lungs. It has been observed that in a decidedly noteworthy proportion of active and progressive cases the first lesions—those responsible for the initial symptoms of the disease—are located below the clavicle, while the apices remain free from pathological changes for some time. This is what some writers have called the "new doctrine" of subclavicular localization of fresh and active tuberculosis. Further research has confirmed the traditional teaching that apical lesions are very common, more common than those located below the clavicle, but they are, in the vast majority of cases, sclerotic in nature and display no tendency to cause symptoms of phthisis, which are disabling and lead to a fatal issue. In fact, it appears that these apical lesions are the ones that are so often found at necropsies of patients who died from other causes, and who during life had not suffered from disease of the lungs.

This "new doctrine" of subclavicular localization of tuberculous lesions is quite old when one considers the work of several British pathologists and clinicians. In his Goulstonian Lectures of 1882 on "Pulmonary Cavities," William Ewart[1] is very explicit in his description of the "so-called apex lesion," which he found much below the apex of the lung in many cases:

"In the later stages of pulmonary consumption, it must be conceded, the vomica commonly extends to the summit of the lung. It is habitual, however, even at this stage, to find the cavity lateral rather than median in its axis; and I may state at once that the extension of a cavity to the periphery is mainly a matter of time. We cannot, therefore, with safety draw a conclusion from the size and position of the late cavity as to the size and situation of the earlier disease. Clinical observation supplies us with valuable evidence in our endeavour to settle the question. *A careful diagnosis will not fail to convince us that the early consolidations are more commonly seated in the subclavicular region than at the apex.* The same fact is often capable of direct demonstration, when at the time of death one of the lungs is as yet but slightly affected. I do not wish to underrate the clinical value of an examination of the supraclavicular space. This is undoubtedly a position in which the signs of the disease are very early perceptible; but I have not encountered breaking down in this situation with as much frequency as in the inner or in the outer subclavicular region." (Italics mine.)

Sir James Kingston Fowler[2] is another British physician who was well acquainted with the subclavicular localization of early tuberculous lesions before Central European clinicians and roentgenologists described them in detail. He emphasizes that:

"the extreme apex of the lung is not often the site of the primary lesion. . . . *It is situated from an inch to an inch and a half below the summit of the lung, and rather nearer to its posterior and external borders.* . . . A second and less usual site of the primary affection of the apex corresponds to the chest wall within the first and second interspaces below the outer third of the clavicle. The lines of extension are usually downwards, so that after a time an oval area of lung is involved, occupying the outer part of the upper lobe. *It is possibly true that the spread of the disease is more rapid when the primary lesion occupies this site.* The lesions in the advanced stages—induration and cavities—are formed by the coalescence and extension of these primary foci." (Italics mine.)

Subsequently Birch-Hirschfeld,[3] Schmorl,[4] Aschoff,[5] and other pathological anatomists showed that the initial lesion of pulmonary tuberculosis is not usually found in the real apex of the lung but lower down.

But these anatomical and clinical observations were neglected for many years, merely because the physical signs of tuberculosis in its earliest stage, if decisive at all, point to the lesion being localized in the apex. It remained for the Roentgen rays to clear up this point. Dr. Harry Wessler[6] of New York seems to have been the first to describe opacities on the Roentgen picture which are "the earliest evidences of the disease," and which "are less often found in what is clinically known as the apex than in the infraclavicular region. Furthermore, the axillary half of the lung is more apt to be involved in the beginning than the mesial half." Then came Dr. Herbert Assmann[7] of Leipzig, who showed that these early lesions in active and progressive tuberculosis of the lung can only exceptionally be demonstrated by physical signs, but are usually found on the Roentgen picture to be located below the clavicle. Since Assmann's paper there have appeared many others—for example, those of Romberg,[8] Lydtin,[9] Redeker,[10] Baemeister,[11] Fishberg,[12] H. V. Morlock,[13] and many others—tending to confirm these observations.

APICAL LESIONS.

It must be emphasized at the onset that the vast majority of tuberculous lesions are found in the apex of the lung, and they remain circumscribed to that region. This point is best shown at necropsies in persons who succumbed to causes other than tuberculosis. Nearly all lesions in the lung which had cicatrized, remained inactive, and gave no trouble during the life of the individual are in the apices. One may also discover them during thorough and careful physical examination of chests of persons who have had no constitutional symptoms of phthisis. These lesions are very often discovered clinically and with the aid of the Roentgen rays during the course of the periodical examinations of the healthy, which are becoming the vogue

* Made in opening a discussion in the Section of Tuberculosis at the Annual Meeting of the British Medical Association, held at Manchester, July, 1929.

in the United States. In patients with extrathoracic tuberculous lesions, as of the skin, the kidneys, the adnexa, the bones, joints, or glands, and who are very often referred for chest examination, the lesions are almost invariably found in the apex, as may be evident from the changes in resonance, breath sounds, and perhaps some adventitious sounds discovered over that region. But it is noteworthy that such patients hardly ever suffer from significant pulmonary symptoms. Their troubles are those of the extrathoracic lesions. In most of these cases, if death ensues because of the tuberculous infection, it results from acute pneumonic phthisis, or more commonly miliary tuberculosis. Similar apical lesions are found in many persons without extrathoracic tuberculosis. They suffer from frequent "colds"; at times they have subfebrile reactions lasting a few days or weeks. They are rather slim, though now and then we meet some who are more or less obese, especially those who have pulmonary emphysema in addition to the apical lesions. They may spit blood, even copious haemorrhages may occur, and tubercle bacilli may be demonstrated in the sputum. Apical retraction is perhaps evident on inspection of the thorax, and the changes elicited by auscultation and percussion are those described as typical of early tuberculosis. But with or without any therapeutic intervention they are doing well, as a rule. They live indefinitely unless carried off by some intercurrent disease. They are diagnosed as tuberculous by ultra-cautious physicians, and they supply the clinical material for any "cure" which happens to be introduced at the time, proving the efficacy of the particular remedy or method of treatment. They also supply the "early" and the "curable" cases considered ideally suitable for sanatorium treatment. These lesions are apparently the residua of childhood infection which had become obsolete, only to be discovered when a physical examination of the chest is made for any reason.

During recent years there has appeared evidence to the effect that lesions limited to the apex of the lung only exceptionally develop into active and progressive tuberculosis which requires treatment, and which is the cause of death in about 10 per cent. of civilized humanity. Statistics collated by Bräuning,[14] Lydtin,[9] Redeker,[10] Kayser-Petersen,[15] and others tend to show that only about 7 per cent. of these persons with apical lesions develop active and progressive tuberculosis or die from this disease. From figures given later on it will be seen that while these findings are more favourable than our own, yet it must be acknowledged that the outlook in real apical tuberculosis is good in the large majority of cases.

That there is a type of pulmonary tuberculosis which runs a benign course has been known for a long time. We speak of "abortive tuberculosis," which presents symptoms and signs of the disease, even tubercle bacilli in the sputum, but the patient recovers quickly with or without treatment. In many cases this is the end of the trouble, but in others the symptoms recur at irregular intervals, the patient being considered either as "subject to colds," or as tuberculous, depending on the skill in physical diagnosis of the physician or the employment of the Roentgen rays. This group, which is not inconsiderable, is usually made up of persons with tuberculous lesions limited to the apical region. It also makes up the large contingent of "repeaters" at sanatoriums; patients admitted with minimal lesions, kept for a few months, and discharged with the disease arrested or cured, to be readmitted within a comparatively short time, again as incipient cases, to be shortly discharged for the same reasons as on previous admissions. It is remarkable that they nearly always remain "incipients." I have cases at Bedford Hills Sanatorium and at the Montefiore Hospital that have been in these and in other institutions five and even more times, and the lesions, limited to the apices, are found to be of the same character and extent at each admission. We meet bearers of these apical lesions in droves at health resorts which accommodate well-to-do consumptives, who feel that they must stay at the sanatorium for life, and claim that as soon as they return home they have a relapse. They nearly all have apical lesions, if any at all, which never spread, and show no symptoms of progression. Some French authors have spoken of them as recurrent apical pleurisy, while German physicians, notably Krönig, described them as "collapse induration," altogether of non-tuberculous origin and occurring mainly in mouth-breathers. With a view to differentiating them from progressive phthisis Neisser[16] spoke of these apical cases as "tuberculosoid." What had not been emphasized until recently, however, is the fact that these lesions are limited to the apex, and remain so limited indefinitely.

Correlating these cases with the fact that nearly everybody has been infected with tubercle bacilli during early life, it would appear that they originate in the primary infection which took place during childhood, and, because of the strong resistance of the individual concerned, the lesion cicatrized. In some instances we may note that the lesion became calcified. As a rule they do not require prolonged and costly treatment; there is no reason for banishing them to distant climes. It is only phthisiophobia that urges them to remain away from home for years, as is the case with many in sanatoriums and health resorts. They are easily diagnosed by the physical signs, which are those described in textbooks and monographs as pathognomonic of "incipient" tuberculosis, and with the aid of the Roentgen rays, which show clearly shrinkage of one or both apices. In some cases of fibroid phthisis of the emphysematous type, or those showing the stigmata of diffuse tuberculous fibrosis, there are physical and Roentgen signs of apical lesions, unilateral or bilateral. They live on for years in comparative comfort. I have had under my care some who have thus continued at their avocations for over twenty years. It is probably true that in nearly all such cases the onset is very insidious, but inasmuch as the usual reasons for their seeking medical advice are transient acute or subacute episodes, the onset is at times put down as more or less sudden. As has already been mentioned, many are discovered during a routine examination, but more often as a result of some intercurrent non-specific respiratory infection, influenza, or "grippe." Real exacerbations of the tuberculous lesions, which occur now and then, are usually short-lived; recovery is rapid, and a change of environment for a few weeks works magically. One thing is to be mentioned: these cases are the backbone of the favourable sanatorium statistics. Without these apical cases, the results of sanatorium treatment in climatic resorts would not make as good a showing as they do.

SUBAPICAL LESIONS.

Pulmonary tuberculosis of more serious prognostic significance generally begins differently, has a relatively abrupt onset, and the lesion is located below the clavicle in the vast majority of cases. A patient, who has no history of previous pulmonary complaints, who had not been "subject to colds," begins to feel tired at the least exertion, coughs, has night sweats, and, in some instances, expectorates blood. Physical examination of the chest does not reveal signs which would clinch the diagnosis of a localized lesion in the lung. There may be impairment of resonance, perhaps some prolongation of the expiratory murmur in the region of the second or third interspace, or the interscapular space, but this is not sufficient to make a diagnosis of a localized lesion. For this reason valuable time may be lost unless microscopic examination of the sputum reveals tubercle bacilli, or the Roentgen examination discloses a soft, cloudy patch, isolated in the midst of apparently healthy lung tissue, just below the clavicle and often toward the axillary portion of the lung. The nature of the patch is broncho-pneumonic, of the type seen in primary tuberculosis in children, or in tuberculous pneumonia in adults. In most cases it is found on a level with the second or third interspace, but it may be located lower down, even in the lower lobe. It may be small, the size of a cherry, or larger, involving the greater part of the upper lobe. The apical region appears free from pathological changes. The shadow may be distinct and clear-cut, but in most cases it has an irregular outline. Inasmuch as softening of the caseous material may take place rapidly, the formation of excavations occurs at times very soon, and we may find at the first Roentgen examination signs of an isolated cavity surrounded by a thin shell in the midst of unaltered lung.

These early lesions occur mainly in young persons and adolescents, though I have met with many in persons over 45 years of age. The age incidence of subapical lesions as compared with apical is shown in the appended table which Dr. Arnold Shamaskin and I compiled from an examination of radiograms of 1,000 patients admitted to Bedford Hills Sanatorium within the past five years. Of these, in only 167 cases could the location of the first lesion be determined with a certain degree of exactitude.

TABLE I.—*Age Incidence of Apical and Subapical Lesions.*

Age.	Subapical lesions.		Apical lesions.	
	Number.	Per cent.	Number.	Per cent.
Under 20 years	56	35.7	8	13.5
20 to 25 ,, ...	29	27.1	14	23 3
25 to 35 ,, ...	30	28.9	19	31.7
35 to 45 ,, ...	9	8.4	12	20 0
45 and over	3	2.8	7	11.7

It will be noted that over 60 per cent. of subapical lesions manifest themselves in persons under 25 years of age, as against 36 per cent. of apical lesions. On the other hand, the percentages are 11 and 32 respectively in persons over 35 years of age. In our daily practice we meet with these subapical cases more often in individuals under 25 years who feel out of sorts, but in whom careful physical exploration of the chest reveals nothing definite. Unless a good radiogram is taken, or tubercle bacilli are found in the sputum, the patient is apt to be treated for neurasthenia, bronchitis, "gastritis," or any other minor ailment. It is only after the lesion has spread upward, involving the summit of the lung, and physical signs are easily elicited, that the diagnosis of tuberculosis is made. It is for this reason, perhaps more than any other, that these subapical lesions formerly eluded us. It also appears that chronic phthisis without any definite physical signs, often described by authors of former generations, also pulmonary haemorrhages in persons without signs of lung lesions, were often manifestations of subapical lesions.

It is a peculiar fact that the first cases of subapical tuberculosis reported were mainly in individuals who had been exposed to contact infection with tubercle bacilli to a greater degree than the average person—such as medical students, bacteriologists, physicians in hospitals and sanatoriums, nurses, relatives of patients with active tuberculosis, etc. Hence the conclusion was drawn that they are the result of recent exogenous superinfection. The fact that the *x*-ray appearance of the lesion is not unlike the kind seen in children in whom the infection is undoubtedly primary seemed to confirm this view. But further observation has shown that many more cases are discovered in individuals who had not been unduly exposed to potential sources of infection. Moreover, in the vast majority of our cases we find sufficient evidence of earlier tuberculous infection, and only rarely are the regional lymph glands found to be enlarged, which would be the case in primary, exogenous entry of the virus. This sort of lesion is also encountered in patients with old extrathoracic tuberculosis.

It is well known that persons unduly exposed to tuberculous infection are just the ones who, when feeling out of sorts, will utilize modern methods of diagnosis earlier than others. Physicians, nurses, and relatives of patients with active tuberculous lesions will have their sputum examined, and *x*-ray films made, as soon as they cough or lose in weight; and for this reason these lesions, which can only be discovered very early, are found more often in this class of people.

The nature of these early lesions has been the subject of considerable discussion. Anatomic and radiographic studies of tuberculous lesions of this type in children and in adults show clearly that they are broncho-pneumonic. The recently emphasized fact that they often undergo involution—that is, are absorbed, leaving hardly any trace—is interesting, even though it has been known for a long time that tuberculous lesions are very often absorbed. On the other hand, some authors speak of them as perifocal inflammatory processes, only the centre of which is tuberculous and is surrounded by a large area in which an allergic reaction has so increased the density of the lung, particularly by a process of exudation, that the characteristic radiographic appearance is produced. According to this conception the tuberculous lesion is rather small, and when the perifocal anatomically non-specific exudate is absorbed hardly any traces may be left as far as the *x*-ray picture shows. Unfortunately there is little actual anatomic evidence that such is the actual course of events. Nevertheless there is a great deal in favour of this view when we recall other allergic reactions in the tuberculous. Thus injections of excessive doses of tuberculin produce the well-known focal reaction because of tissue allergy, which generally disappears sooner or later. After pulmonary haemorrhages also we often observe such phenomena in tuberculous lungs; they can be readily followed by any method of examination, physical or radiographic—the spread of the lesion being temporary and disappearing soon after the haemorrhage ceases.

PROGNOSIS.

It has already been mentioned that the prognosis in apical lesions is more favourable than in the subapical. Those with lesions limited to the apices last much longer, and may continue at their avocations for many years. This point is well shown in Table II.

TABLE II.—*Duration of the Disease.*

Age.	Subapical lesions.		Apical lesions.	
	Number.	Per cent.	Number.	Per cent.
Under 1 year	28	25.2	8	13.3
1 to 3 years	48	43.9	12	20.0
3 to 5 ,, ...	20	18.7	9	15 0
5 to 10 ,, ...	9	8.4	12	20.0
10 and over	2	1.8	19	31.7

Among the patients at the Bedford Hills Sanatorium less than 2 per cent. with subapical lesions had been sick for ten years or more, as against 32 per cent. of those with apical lesions; over five years, the percentages are 10 and 52 respectively. The main contingent of progressive cases, leading to serious illness and ultimately to a fatal issue, is derived from the subapical group.

We have found that patients with apical lesions have generally mild, and but rarely severe, brief exacerbations of symptoms at irregular intervals, while prolonged, continuous, or remittent febrile reactions are uncommon. In fact, the enormous number of patients in sanatoriums that run an afebrile course with slight febrile episodes which abate soon are mainly those with lesions limited to the apices. Among our patients at the Bedford Hills Sanatorium we found that 70 per cent. of those with apical lesions ran an afebrile course, while of those with subclavicular lesions only 42 per cent. were afebrile. Blood-spitting, on the other hand, is about as common in one group as in the other, but this refers only to streaked sputum or mild haemoptysis. Copious haemorrhages are more common in patients with subclavicular lesions. The following table illustrates this point:

TABLE III.—*Incidence of Pulmonary Haemorrhage.*

Haemoptysis.	Apical lesions.		Subclavicular lesions.	
	Number.	Per cent.	Number.	Per cent.
None	28	46.7	42	39.2
Streaked sputum	15	25.0	33	21.6
Copious haemorrhages ...	17	28.3	42	39.2

EVOLUTION OF THE SUBCLAVICULAR LESION.

The progress of the subclavicular lesion can be followed only with the aid of serial radiograms. The lesion may remain unaltered for weeks and months. With the improvement in the general condition involution may take place and the infiltration is absorbed, leaving merely linear markings denoting fibrosis. In other cases signs of thickened interlobar pleura remain. In rare instances calcification of the lesion takes place and there remain sharply demarcated, homogeneous spots immediately below or above the clavicle. The patient may remain well indefinitely. The number that terminate thus is much larger than is generally appreciated.

In active and progressive cases the lesion usually extends upward, involving the summit of the lung, and there results the common variety of chronic phthisis in any of its protean forms. It is then that it can be easily diagnosed by the physical signs, and for this reason the really early lesions were generally overlooked prior to the universal application of the Roentgen rays for diagnosis. In some patients the infiltration extends both upward and downward, so that an entire lobe is involved in a short time, at times a whole lung. The clinical picture is then that of acute pneumonic phthisis. I have seen cases of this type which ran their complete course within a few weeks.

In a large proportion of cases the lesion caseates, softens, is expectorated, and finally leaves an excavation. These *early cavities* may form quickly, within a few weeks after the first symptoms of the disease appear, and in fact even before one has any suspicion that he is dealing with tuberculosis. I meet with such cavities now and then in patients who had felt out of sorts for one or two weeks only. As a rule, these cavities are not revealed by physical signs; only the Roentgen rays disclose them. They have certain characteristics which differentiate them from excavations formed later in the disease. They appear on the radiogram as spherical or oval in shape, isolated in the midst of apparently healthy lung tissue, surrounded by a sharply demarcated border consisting of a thin or moderately thick wall; in exceptional cases a shifting fluid-level may be noted at the most dependent part. It is noteworthy that the area within the walls of the cavity may exhibit lung markings not unlike those in the remainder of the lung, thus demonstrating the integrity of the parenchyma in front of or behind the excavation.

These early cavities are usually located below the clavicle, though at times we find them in any part of the lung, even in the lower lobe. They may be multiple and coalesce to form the well-known honeycomb picture. Cavities formed later in the course of disease have thick walls, which are surrounded by infiltrated lung tissue, while around the early cavities the surrounding lung is apparently healthy. In many instances of late cavitation we find the lobe in which they are located completely obscured by a shadow in the midst of which there is brightness of variable degree. It is also noteworthy that in late cavities the mediastinal organs and also the trachea are, as a rule, drawn toward the affected side, owing to shrinkage of the lung, which is not common in cases with early excavations.

In exceptional instances these early cavities heal, as has been observed by all those who have taken serial radiograms of tuberculous patients. The circular shadow disappears, leaving linear markings pathognomonic of fibrosis or at times no visible trace at all. In fact, some authors have for this reason spoken of these "annular shadows" as representing pleural adhesions, localized pneumothoraces, etc., and not at all as excavations of the parenchyma. But more careful studies have shown conclusively that, with but extremely rare exceptions, they are cavities even though they heal.

In many cases of these subclavicular infiltrations the lesion spreads along the lymphatics so that on the radiogram there are dots and spots running from the original lesions outward and downward. In still others caseating areas suddenly appear in other parts of the same or the contralateral lung. Now and then we meet with a case in which numerous isolated lesions of various sizes appear in one or both lungs simultaneously. The main characteristic of these lesions is that they develop quickly, and do not proceed by the direct continuous extension of the original lesion. An extensive lesion means, as a rule, coalescence of several of these infiltrations. As each new infiltration appears there is an exacerbation in the symptoms.

THERAPEUTIC INDICATIONS.

The differentiation of apical from subapical lesions is of immense therapeutic importance. To begin with, the prophylaxis of clinical tuberculosis is narrowed down mainly to the latter group. Among our patients at Bedford Hills Sanatorium we found that "open" tuberculosis"—that is, the type of case in which there is expectoration of sputum containing demonstrable tubercle bacilli—is uncommon in the apical group. Tubercle bacilli were found in the sputum of 66.4 per cent. of patients with subclavicular lesions, as against only 15 per cent. with apical lesions. It is thus clear that strict isolation, the backbone of tuberculosis prevention, is not indicated in some 85 per cent. of apical cases. And prophylaxis is considered one of the main reasons for institutional treatment of tuberculosis.

It appears, further, that prolonged and costly treatment is unnecessary in the vast majority of apical cases. We have shown that they remain in good condition indefinitely, and only rarely develop active and progressive phthisis. The finding of signs of apical condensation, such as impairment of resonance, prolonged expiratory murmur, or even some adventitious sounds limited to the apical region in a patient with symptoms of a common cold, or "grippe," and radiographic confirmation that the changes are limited to the apical region, does not invariably mean urgency of climatic, institutional, or operative treatment. We may most often look to an early recovery after a few weeks' rest; perhaps a change of environment for a month or so will be effective in restoring the patient to health. Indeed, from my observations in sanatoriums in various countries it appears that a large proportion of patients with these apical lesions could be discharged with benefit to themselves, the institutions, and the communities which are charged with their care.

It is different with patients having subclavicular lesions. While many recover within a short time under any form of treatment, a large proportion are in need of careful attention. They have the symptoms of acute, subacute, or chronic phthisis which urgently requires treatment. Many are benefited by rest, at home or in institutions, but others require artificial pneumothorax. The latter should be induced early, before the formation of pleural adhesions which are responsible for so many failures in collapse therapy. Induced early, when the filtration is still limited and circumscribed within the parenchyma, we usually find a free pleural cavity, so that it is feasible to collapse the entire or the greater part of the affected lung.

HILUS TUBERCULOSIS AS AN IMPORTANT CAUSATIVE FACTOR IN PULMONARY TUBERCULOSIS IN ADULTS.

BY

D. J. GAIR JOHNSTON, M.B., CH.B., D.P.H.,

BIRKENHEAD.

THE term "hilus tuberculosis" is used for convenience, and in a comprehensive sense, to include tuberculosis of all or any of the different groups of bronchial glands. An almost universal distribution of tuberculous infection in the human subject has been found by so many observers that it is now accepted as a proved fact. The present investigation has been carried out with a view to determining how far it is possible to diagnose tuberculous infection from clinical signs and symptoms only, and whether there is any direct connexion between such infection and pulmonary tuberculosis. The period of observation extended over ten years, and involved the examination of over 20,000 children between the ages of 5 and 14, and the re-examination at intervals of three to six months of all those showing definite evidence of departure from the normal. The first thing that impresses itself on the observer who has examined even a few hundred healthy chests is that there is no fixed normal. The normal varies within fairly wide limits, and a long apprenticeship is required to establish confidence in deciding which cases fall within the normal and which are definitely outside it.

The mass of evidence obtained, often apparently very contradictory, was very perplexing during the earlier period of the investigation, but slowly the accumulated evidence of years tuned the mind to a more or less definite line of thought, which appears to offer a reasonable explanation for all the varying phases and stages of the infection. The physical examination followed the usual lines, and does not require to be given in detail. It is advisable, however, to emphasize the necessity of using the very lightest percussion if the finer shades of dullness are to be successfully determined. Tidal percussion should always be mapped out, although, at the apices, it was found to be less valuable in children than in adults, and the same may be said of Krönig's sign. The "reflex bands of dullness" (Clive Riviere) afford a most reliable sign of invasion of the lung parenchyma. They are not always easy to make out, but when present are very significant. They were repeatedly looked for in children, but very seldom found, probably because definite invasion of the lung parenchyma in children is relatively rare. Granular breathing is highly suggestive of tuberculous infection, and can sometimes be heard over a whole lung; but it does not necessarily mean that the tubercle bacilli have invaded the lung tissue.

The process of weeding out all cases showing evidence of tuberculous infection, and the exclusion from school of the worst cases for suitable periods, was productive of much good. This is shown by the following comparative figures:

Years.	Tuberculous infection.
1913	15.4 per cent.
1914	14.9 ,,
1920	9.1 ,,
1921	7.2 ,,
1922	4.8 ,,
1923	4.6 ,,

The period 1914–20 covers the war period, when the work was entirely suspended.

A careful survey of the teeth, tonsils, and cervical glands was made, and pathological evidence of parasternal and paravertebral glands looked for. An attempt was made to correlate the condition found with evidence of tuberculous infection; also what, if any, connexion existed between physical signs of enlarged bronchial glands, and the distance down the spine to which definite tracheal breathing extended. The following table shows the percentage of children, out of a total of 1,918 examined, who were found to be defective in each of the eight conditions stated:

	A.	B.
1. Teeth	27.7	13.3
2. Tonsils	8.0	4.3
3. Adenoids	4.7	2.0
4. Nose (chronic catarrh)	22.2	14.3
5. Cervical glands	90.7	45.5
6. Family history of phthisis	20.1	7.8
7. Defective nutrition	50.7	26.8
8. Deformities of chest	4.0	0.9

A refers to cases of tuberculous infection; B refers to all cases.

These figures seem to show a definite connexion between septic conditions of the nasopharynx and the prevalence of tuberculous infection. The age incidence worked out at 33 per cent. at 6 years; 46 per cent. at 9 years; and 21 per cent. at 13 years.

Although a well-marked case of hilus tuberculosis is easy to detect, the less well-defined cases are difficult. The following may be regarded as a typical well-defined case:

A boy, aged 9 years, was on examination found to be pale and flabby, but fairly well nourished; he gave a history of frequent colds, and of cough and lassitude for a prolonged period. Over the chest and neck, particularly on the right side, there were numerous prominent veins; the right supraclavicular glands were palpable and the right paravertebral dullness was definitely increased. At the apex of the right upper lobe expiration was greatly prolonged, and there was blowing respiration over the right interscapular region, with tracheal breathing extending to the sixth dorsal spine.

The following case is also of interest:

A girl, aged 13 years, was examined because she had persistent cough, was very short of breath, and did not feel well. Physically she was of the large flabby type so often associated with tuberculosis. Examination revealed numerous fine crepitations all over both lungs; the heart was normal. A bad prognosis was given, but in three months the lungs showed no abnormality.

There was no other case in the series quite like this one, but a fair number showed signs confined to one side, with weak breath sounds and definitely diminished tidal percussion and expansion, suggesting pressure by enlarged bronchial glands. Granular breathing was a fairly common accompaniment.

An attempt, involving the special examination of 300 children, was made to gauge the diagnostic value of tracheal breathing. Four groups were taken, as follows: A, no evidence of tuberculous infection; B, slight but definite changes at an apex; C, definite physical signs at an apex; D, definite areas of localized crepitations.

Distance heard.	A.	B.	C.	D.
7th cervical or 1st dorsal	80	58	27.4	26.6
2nd dorsal to 3rd dorsal	12	24	26.0	20.0
4th dorsal to 7th dorsal	8	18	46.6	53.4

Experience shows that tracheal breathing does not commonly extend beyond the first dorsal vertebra in strictly normal cases, and this observation supports the view that it is heard more frequently beyond the first dorsal vertebra in infected cases.

Many of the children showed physical signs which in an adult would be regarded as definite evidence of pulmonary tuberculosis, yet their history, and often the final examination, entirely belied that assumption. The condition would remain, year after year, with little or no change, and the child might, and not unfrequently did, enjoy good health. In some cases all the physical signs entirely disappeared. It was not uncommon to find, on routine examination, the following signs at an apex: retraction, delayed movement, impaired resonance, broncho-vesicular breathing, and increased vocal resonance. In addition, cough and lassitude were complained of, and even a family history of pulmonary tuberculosis was obtained. In such circumstances it is difficult to divorce the mind from the opinion that there is definite tuberculous invasion of the lung parenchyma, yet numerous such cases have been observed for years, during which, in many cases, the children enjoyed reasonably good health, and finally left school with the physical signs more or less unchanged. At first it was assumed that the physical signs indicated a healed lesion, and they were regarded seriously; but as years went on that explanation, although very tempting, simply would not fit the cases. If a healed lesion of such dimensions existed, then some evidence of destruction of lung

tissue and its replacement by fibrous tissue would remain, but in quite a number of cases all the physical signs entirely disappeared, including the retraction. Such a history does not suggest a healed lesion, and the clinical picture was not in conformity with a simple apical collapse.

A girl, aged 6 years, was examined and the physical signs were retraction, impaired resonance, and broncho-vesicular breathing at the apex of the right upper lobe; she had also palpable cervical glands, increased paravertebral dullness, spinal telangiectasis, and tracheal breathing to the seventh dorsal vertebra. In six months there was no retraction and no dullness. After a further six months the physical signs were reduced to weak inspiration and prolonged expiration and tracheal breathing to the fifth dorsal vertebra. Six months later the lungs were normal and tracheal breathing was heard only to the first dorsal vertebra.

Here we have definite physical signs at an apex, accompanied by definite signs of glandular enlargement, and both clearing up simultaneously.

The examination of a boy, aged 6 years, revealed the following signs: impaired resonance and broncho-vesicular breathing at the apex of the right upper lobe; also dullness, cavernous breathing, bronchophony, and numerous crepitations in the right axilla. After an interval of seven years the signs at the right apex were unchanged, but modified at the right axilla. The left axilla now showed marked bronchial breathing and numerous crepitations. One year later the only signs were impaired resonance and broncho-vesicular breathing in the left axilla. At the first examination the symptoms were cough, lassitude, cold night sweats, and slight staining after coughing. The cough persisted throughout, but the other symptoms were less evident. The cervical glands were much enlarged and tracheal breathing extended to the sixth dorsal vertebra. The patient was a typical street arab, received the minimum of parental care, and was up at 7.30 every morning delivering milk. If there was definite invasion of the lung parenchyma it is difficult to believe that he would have improved, as he certainly did, in spite of such adverse conditions.

Another case is that of a girl, aged 9, who was under observation for one year as a case of hilus tuberculosis. She suddenly became ill, and on examination revealed the usual right apical signs, greatly aggravated. A pneumonic patch was suspected, but the advent of a measles rash made the position clear. Within a week the apical signs returned to their original condition; the aggravation was evidently due to an acute infection of already infected glands.

Another type of case which caused difficulty was that of the child in whom was found an area of localized crepitations. This consisted of small patches of lung area, always in the lower or middle lobe, where crepitations could be heard. The crepitations were very fine, almost consonating, and heard at the end of inspiration only; they were very persistent under all conditions. The respiratory sounds were generally weak, owing to the modifying influence of the fluid in the air cells, and impaired resonance was found over the larger patches. Almost every such child was obviously below par, had a persistent cough, and complained of lassitude; important confirmatory evidence was volunteered by the teachers that such children were educationally backward and often absent from school. The localized patches of crepitations persisted for months, sometimes for years, but they generally cleared up without leaving any permanent evidence. Poor health accompanied the crepitations, but improvement always followed the clearing up of the local conditions.

Some Illustrative Cases.

Case 1.—The patient, a boy aged 8, gave a history of recent symptoms of pleurisy with cough and lassitude for a month. There were a considerable number of crepitations in the left lower lobe. Six months later the crepitations were still present, tidal percussion was definitely lessened, and impaired resonance and prolonged expiration were found at the apex of the right upper lobe. The left supraclavicular glands were palpable and there was definitely increased paravertebral dullness. An examination in ten months showed no abnormality. His weight increased by 12½ lb. in eighteen months.

Case 2.—A girl, aged 11, had an extensive patch of crepitations in the right axilla, which persisted for three years, but ultimately cleared up without leaving any permanent evidence. Her weight increased by 31 lb. during the period.

Case 3.—A boy, aged 13, had bronchial asthma accompanied by weak breath sounds over the whole of the left lower lobe, as well as retraction of lung and diminished tidal percussion. There was weak inspiration at the apex of the right upper lobe down to the third rib, and tracheal breathing to the sixth dorsal vertebra. The increase of weight in two years was 14 lb.

Case 4.—A boy, aged 12, had numerous crepitations in the left axilla between the sixth and eighth ribs, extending from the nipple line to the posterior axillary line. Tidal percussion was diminished. At the apex of the right upper lobe there were retraction, impaired resonance, weak inspiration, and prolonged expiration. The cervical glands were much enlarged and the patient had a persistent cough. At the end of one year the signs at the right apex remained, but the other signs had cleared up.

These cases demonstrate the persistence of the local crepitations over a number of years, accompanied by evidence of pressure by enlarged bronchial glands. All showed a steady, but somewhat irregular increase in weight, and in none was there any sound justification for believing that the lung parenchyma was invaded by tubercle bacilli. All the signs and symptoms are more reasonably explained as being secondary to pressure by enlarged bronchial glands, the crepitations being probably due to interference with the free circulation by infected broncho-pulmonary glands.

The apical signs were found at the right apex only in 62 per cent. of cases, the left only in 6 per cent., and in both in 32 per cent. On the other hand, the localized crepitations were found in the left lower lobe in 58 per cent. of cases, and in the right in 42 per cent. Cough and/or lassitude were present in 87 per cent., nutrition was below normal in 83 per cent., and at 13 years of age the average weight was 10 lb. below the average.

It might be argued that such conditions may be true for children, but are not likely to be found in adults. A year's duty in the Ministry of National Service, when many thousands of adults of all classes of society were examined, afforded an excellent opportunity to test this point. As deputy commissioner in charge of a large industrial area I personally examined all cases showing definite evidence of departure from the normal, and found that the conditions at the apices of the upper lobes, and the localized crepitations in the lower lobes, closely resembled those so familiar in children. A similar opportunity for repeated examinations was not available, but the broad fact remains that such cases were by no means uncommon, and occurred in men who were presumably well and carrying out their ordinary duties. In private practice one frequently finds cases which show physical signs and symptoms highly suggestive of definite pulmonary tuberculosis, without the infection having passed beyond the bronchial gland barrier; and that when invasion of the pulmonary parenchyma does occur it is not infrequently due to the rupture of infected bronchial gland contents into a bronchial tube.

Reports of Cases.

Case 1.—The first case is that of a lady in whom the presence of tuberculous bronchial glands was diagnosed two years prior to an acute exacerbation. She complained of great shortness of breath, violent and persistent cough, and great lassitude. There was no sputum. The physical signs at the apex of the right upper lobe were slight retraction and delayed movement, impaired resonance, broncho-vesicular breathing, but no adventitious sounds. The physical signs varied from time to time, but the symptoms persisted. During the exacerbation she developed an evening temperature; numerous crepitations were heard in the right infraclavicular region, and the other physical signs were aggravated. In spite of these very suggestive signs, I formed the opinion that there was no invasion of the lung parenchyma. A month's rest in bed brought the patient back to her original condition. She was afterwards examined by a leading authority on tuberculosis, who reported that "the right apex was becoming aggressive," and advised her to winter abroad. This she did, and was examined there by another specialist in tuberculosis, who, after an *x*-ray examination, agreed that the infection was confined to the bronchial glands, there being no evidence of pulmonary tuberculosis.

Case 2.—A boy, aged 17, was under observation as a case of hilus tuberculosis for one year. A sudden acute illness developed, and examination revealed impaired resonance and broncho-vesicular breathing at the apices of both upper lobes, particularly the right; also blowing, respiration in the interscapular regions, and tracheal breathing to the sixth dorsal vertebra, but no adventitious sounds. The pulse rate was 120, respiration rate 30, and the temperature 102° F. or more in the evening, 99° F. in the morning. He had cold night sweats, a very violent cough (no sputum), and the clear bright eyes of tuberculous toxæmia. His condition was very grave for several weeks, and, although an assurance was given that the lungs were free at the moment, there was definite risk of acute pulmonary tuberculosis. Gradually the whole condition quietened down without showing any evidence of pulmonary invasion, and he has enjoyed good health for over two years, working long hours every day.

Case 3.—A girl, aged 14, in whom hilus tuberculosis had been diagnosed three years prior to her illness, suddenly developed what was supposed to be a cold; two days later, however, examination showed absolute dullness over the whole left lower

lobe, with bronchial breathing, bronchophony, and patches of crepitations irregularly scattered throughout the lung. The evening temperature was 100° F., morning temperature 99⅘ F. or normal; the pulse rate 80, and respiration rate 21. The patient had severe cough (no sputum), cold night sweats, and the clear bright eyes of tuberculous toxaemia. She remained seriously ill for a month, but in two months she was convalescent, and in three months the affected lung showed no abnormality.

Cases 2 and 3 are in marked contrast. In Case 2 there was acute tuberculosis of the bronchial glands only, and every evidence of acute toxaemia. In Case 3 the toxaemia was obviously less, although the lung was extensively involved. This would seem to suggest that in Case 2 there was a definite acute tuberculous infection, whereas in Case 3 the condition was probably caused by an enlarged and adherent tuberculous gland suddenly opening into a bronchial tube, distributing its contents, largely consisting of caseous material with a minimum of tubercle bacilli, into the corresponding lung. This would account for the much more favourable prognosis in the so-called "acute pneumonic phthisis," as compared with the more deadly "broncho-pneumonic" type, in which there is diffuse and profuse infection, probably from acutely inflamed glands, either by an extensive retrogressive spread, or by the passing of large numbers of virulent tubercle bacilli into the blood stream.

Case 4.—A male, aged 37, was under observation for two years suffering from periodic attacks of bronchial asthma, with violent and persistent cough and great lassitude. Repeated examinations revealed crepitations over large areas of the lungs, sometimes in one situation, sometimes in another, and occasionally almost entirely absent. No definite clinical signs of enlarged bronchial glands or of tuberculous invasion of the lung parenchyma were present. There was an old history of pleurisy; the sputum was negative. The patient was suddenly taken acutely ill, and a large consolidation was found at the apex of the right upper lobe, extending to the third rib, and tubercle bacilli were found in large numbers in the sputum. In view of the fact that the lung parenchyma showed no previous evidence of *tuberculous invasion*, old or new, it is hardly likely that a large consolidation, extending to the third rib, could have occurred in such a brief period, except by a sudden mass infection from such a source as an infected gland.

Case 5.—A male, aged 47, gave a history of persistent cough and lassitude for one year prior to his illness; repeated examinations of the lungs were negative. It is of interest to note that the "reflex areas of dullness" were absent. He was suddenly taken ill with influenza-like symptoms, but a physical examination showed, at the apex of the left upper lobe, delayed movement, impaired resonance down to the third rib, broncho-vesicular breathing, and fine crepitations over the whole affected area. The evening temperature was 100° F., morning temperature 99° F. or normal, and the pulse rate 90 to 100. Although absent before, the reflex areas of dullness were now most obviously present, and the sputum was positive. In three months he was sent to a sanatorium, and the *x*-ray report was as follows: "There is definite infiltration about the left middle zone and at the left apex. Probably, too, the right upper lobe can be looked upon as slightly abnormal. But on the whole the chest seems to be but moderately slightly involved with tuberculosis."

The usual explanation of this sort of case is that an old lesion has been suddenly lighted up by an attack of influenza. In the first place, there was no old lesion, and, secondly, there was no influenza. The symptoms could, and there is every reason to believe that in this case they did, arise from the shock of a sudden invasion of the lung parenchyma. This would quite obviously give rise to influenza-like symptoms. On the other hand, a sudden invasion from a bronchial gland would account more satisfactorily for all the details of the case, including the preceding persistent dry cough and the large area so quickly affected. The patient's splendid recovery with the minimum of physical signs remaining also seems to support this view. The final sanatorium report was: "His physical signs—never very well marked since admission—are less than ever."

Since writing the above I have again had this patient under treatment. On April 26th, just over one year since his first illness, he complained of cough, did not feel well, and had a temperature. Examination was completely negative. Four days later there was a sudden invasion of the whole left lower lobe, very similar to that of Case 3. This relapse gives further support to the original diagnosis.

No attempt is made to discuss the controversial question of path of infection, but merely to state clinical facts, as observed over the long period of fifteen years.

Conclusions.

1. Hilus tuberculosis can be demonstrated clinically in a relatively large percentage of children.
2. In spite of much clinical evidence suggesting pulmonary tuberculosis in children actual invasion of the lung parenchyma is relatively rare.
3. The natural tendency in all cases is towards a cure, although in many cases physical signs will remain which, *in adult life, will be regarded as old healed lesions.*
4. Pressure from enlarged bronchial glands can be demonstrated clinically; it has the effect either of restricting the free flow of air into a lung or of interfering with the free circulation of blood in the lungs, and giving rise to localized areas of oedema, rarely to general pulmonary oedema.
5. Rupture of adherent caseous glands into a bronchial tube is a not uncommon cause of pulmonary tuberculosis.

The diminished death rate from pulmonary tuberculosis is probably due mainly to the lessened risk of infection from "open cases" in the homes, and to the more prompt recognition of early cases. It is unlikely that a further appreciable decrease will occur unless a serious attempt is made to deal with the large number of potential cases *before*, not *after*, the lung parenchyma has been invaded by the dreaded tubercle bacilli.

TONSILS AND ADENOIDS: THEIR MEDICAL AND SURGICAL ASPECTS.*

BY

J. ARNOLD JONES, O.B.E., F.R.C.S.Ed.,

SURGEON IN CHARGE, EAR, NOSE, AND THROAT DEPARTMENT, ROYAL MANCHESTER CHILDREN'S HOSPITAL; SURGEON, ST. JOHN'S EAR AND THROAT HOSPITAL, MANCHESTER.

Introduction.

The subject of "tonsils and adenoids," which has been chosen for discussion to-day, might well be described as a "best-seller," for there is no medical topic which the laity of these islands discuss with more frequency, more verve, and more ignorance than this, not excepting appendicitis itself; while professional *opinion*, always with us in a small trickle, sometimes attains the level of a flood, as witnessed by the spate of letters in the *British Medical Journal* early this year. The subject may be said to have reached its apotheosis with the publication of Irwin Moore's monumental work last year.

For the purposes of this discussion I shall confine my remarks to those conditions produced by chronic sepsis and hyperplasia of these lymphoid masses—that is, to the clinical and pathological conditions generally meant when a patient is said to be suffering from "adenoids and tonsils." Acute conditions and such rarities as calculi of the tonsils will not come within my purview. The palatine tonsils and the third or pharyngeal tonsil, commonly referred to as adenoids, form part of Waldeyer's ring—that group of lymphadenoid tissue in the naso-pharynx and pharynx which surrounds the entrance to the respiratory and alimentary passages.

The function of the tonsils is still *sub judice*; various theories have from time to time been put forward, but it would seem most reasonable to regard them as organs for the defence of the respiratory and digestive tracts during the early years of childhood. As StClair Thomson succinctly puts it:

"The ages in which they are most in evidence, their situation, their structure, the recognized emigration of lymphocytes through their epithelium, their frequent enlargement with an infectious process, the frequency with which, when their resistance is overcome, they appear to be starting-points for infection, their lasting hypertrophy after prolonged or repeated infections, experimental observations which show that they serve as ports of entry for infection and their normal involution at puberty, all appear to confirm this view."

* Read in opening a discussion in the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Manchester, 1929.

When a tonsil becomes chronically hypertrophied or diseased it loses its defensive powers and comes to resemble a choked filter. This is borne out by the greater frequency with which children possessing these hypertrophies contract infectious diseases and the severity of the ear and throat complications in such cases.

It will now be convenient to discuss the question of adenoids and tonsils separately.

ADENOIDS.

When Luschka's tonsil, as the third or pharyngeal tonsil is sometimes called, becomes hypertrophied and gives rise to definite symptoms, adenoids or adenoid vegetations are said to be present.

The precise cause of this hypertrophy is at present unknown, but it may be stated that in most cases it is due to a lowered vital resistance and an exciting or local cause, such as catarrhal attacks or infectious fevers. William Meyer of Copenhagen, in 1868, was the first to recognize this very common affection of childhood. So widespread is it that no climate or race seems exempt, the negro being perhaps the least affected; but there is no doubt that adenoids are more frequent in damp temperate climates like our own; indeed, Osler has stated that there are more mouth-breathers to the acre in England than in any other country. They are most common between the ages of 3 and 14 years, but may be present at birth, and not infrequently produce symptoms during the first year of life, especially among the poorer classes. This is a fact that I should like to emphasize, and to which I first called attention in a paper in the *Lancet* in 1922. The main symptoms produced in the first year of life are nasal obstruction and discharge. The mother complains that the child has to fight for breath, and takes the breast or bottle with difficulty, as the nasal obstruction prevents the infant from breathing and suckling at the same time. If this obstruction is not removed spoon feeding has to be resorted to, otherwise death from inanition takes place. Such infants are liable to convulsions and vomiting. At the Royal Manchester Children's Hospital I operate on between 30 and 40 of these cases every year, with excellent results, many of the infants being only a few weeks old. I have, indeed, operated as early as the third week. In these cases no anaesthetic is required, and this practically eliminates all risk from the operation. Infants stand the operation remarkably well, and are often enjoying a feed within an hour afterwards.

Symptoms.

Symptoms of adenoids in older children vary within wide limits, depending upon the degree of hypertrophy or sepsis present and the capacity and form of the nasopharynx. They may be classified into the following groups.

1. *Nasal Obstruction, often accompanied by a Mucopurulent or Purulent Discharge.*—I have already referred to these symptoms in the infant. In older children, from 3 years onwards, the classical picture is often met with—open mouth, rabbit teeth, receding chin, pinched alae nasi, high arched palate, noisy respiration, snoring at night, vacant expression, the so-called adenoid facies, etc. It must always be remembered that adenoids can be present causing such marked secondary symptoms—for example, aural—that operation is urgently called for, and yet all the above classical symptoms of nasal obstruction may be absent.

2. *Secondary Affections.*—The most common and most important secondary affection is aural, with consequent deafness, suppuration, and possible sequelae. It is no exaggeration to say that 90 per cent. of cases of deafness in children are due to adenoids. So-called "glandular fever"—recurring febrile attacks with swelling and tenderness in the glands of the neck—is due to local infection of the adenoid tissue of Waldeyer's ring, most commonly the pharyngeal tonsil. Other secondary affections are: chronic cervical adenitis (affecting the glands of the posterior triangle of the neck), defective pulmonary expansion, chronic bronchitis, and gastro-intestinal catarrh.

3. *Reflex Neuroses.*—A long list of these could be compiled, but I will give you only those of which I am sure from personal experience: enuresis, night terrors, and twitchings are frequently benefited by the removal of adenoids. In asthma adenoids should always be removed if present, but they form merely a contributory factor in the disease. The same may be said about chorea, laryngismus stridulus, stammering, and convulsions.

4. *Constitutional Changes.*—These may be physical or mental. The physical include high arched palate, projecting teeth, retracted chest, and pigeon-breast; while among the mental changes are those producing the aprosexia of Guye.

Diagnosis.

The diagnosis of adenoids is usually quite easy. In older children posterior rhinoscopy will reveal the growth in many cases. In younger children, and in those cases in which posterior rhinoscopy is impossible, it may be necessary to palpate the nasopharynx with the index finger; but this is a very disagreeable procedure for the patient, and should only be resorted to when really necessary.

If there are evidences of nasal obstruction in a child, and the examination of the nose and pharynx does not explain it, the presence of adenoids can be assumed as a rule. The other conditions which may simulate adenoids are a naso-antral polypus and a nasopharyngeal fibroma in its early stage.

In infants, when adenoids are strongly suspected, after excluding syphilis, it is my practice to introduce a small cage curette into the nasopharynx, without general anaesthesia. If adenoids are present they are removed. If the nasopharynx is free no harm is done. It must be borne in mind that in the Mongol type of idiot nasal obstruction is frequently present with but a trifling amount of adenoids. As these patients are bad subjects for an operation, I usually leave them alone, unless a very strong case is presented.

Treatment.

If adenoid vegetations are present in sufficient bulk, or are sufficiently septic, to cause any of the cardinal symptoms referred to, in my opinion only one form of treatment at present exists—that is, surgical removal. All palliative treatment is useless, and some forms, such as nose drill, worse than useless.

The best instrument to employ, and one that is used by the majority of surgeons, is StClair Thomson's cage curette, by means of which the adenoid mass is removed in one entire piece. Any lateral prolongations which may not have been included in the sweep of the cage curette are planed down with a simple Gottstein's instrument. The La Force adenotome is much used in America and on the Continent, and has a warm advocate in this country in Dr. Pearce Sturm. I have given this instrument a fair trial, but in my hands it has not proved satisfactory. A point to keep in mind is that the cutting blade of the cage curette should have a sharp edge.

As regards haemorrhage after the removal of adenoids: immediate bleeding is usually very brisk, but as a rule ceases within a few minutes; freely bathing the face and forehead in cold water greatly assists in diminishing this. If the bleeding persists search should be made, under good illumination, for a tag of lymphoid tissue which may have been left behind. This is the most common cause of immediate excessive haemorrhage. Should the bleeding still persist after the removal of a tag, or should no tag be present, a swab of suitable size should be squeezed out of liquid hydrogen peroxide and introduced into the nasopharynx by StClair Thomson's forceps and pressure made for a few minutes. This, in my experience, together with the administration of haemoplastin, is invariably successful, except in the case of a genuine bleeder. Since Dr. Lowndes Yates published his interesting investigations in regard to the relationship of blood-clotting time and the acidity of blood and urine, it has been my practice to give all my patients a course of sodium bicarbonate before operation.

True secondary haemorrhage is rare. I have had two cases in my own practice. One was a hospital patient who had been operated upon and returned home. Her own doctor telephoned to me on the fifth day to say that he had been summoned in the middle of the night for nose-bleeding, and had plugged the nasopharynx and nose. She was readmitted to hospital, but no further bleeding occurred. The other was a very marasmic infant of under 2 months,

who was so badly obstructed that nourishment was taken with the greatest difficulty. This infant was under the care of my colleague Dr. Heywood. On the fourth day after operation attacks of vomiting with blood in the vomit occurred, and death soon supervened. I did not see the patient myself, but death was attributed to secondary haemorrhage from the nasopharynx.

One other fatality from post-operative haemorrhage I have had, making two in all, and I have operated upon well over 12,000 cases. In this case death occurred about eleven hours after operation. I was not notified of the boy's condition until about forty minutes before death took place, and when I reached him he was moribund.

The results following removal of adenoids in suitable cases, especially in cases of nasal obstruction or aural symptoms, can only be described as extremely good. I think that there is no other surgical operation in which results are more promptly beneficial and of such far-reaching effect upon the health of the patient.

Do adenoids recur? The answer is Yes, in a small percentage of cases. Irwin Moore says that statistics show that, if thoroughly removed, there is a tendency to recur in about 10 per cent. of cases. Many cases of so-called recurrence are really cases of inefficient removal, but after these have been allowed for there still remains about 10 per cent. in which recurrences will occur in spite of the most efficient removal. Not only have I seen such recurrences in my own practice, but also some in the practice of well-known colleagues in different parts of the country.

Tonsils.

The indications for tonsillectomy may be set forth as follows:

1. Any interference, night or day, with respiration or with speech.

2. Chronic enlargement of the cervical glands. This may be due to chronic sepsis of the tonsils or to tubercle. The incidence of tubercle in tonsils which have the clinical appearance merely of chronic hypertrophy and inflammation has been studied at various times by different observers with results varying from 0.3 to 9 per cent. Scarff and Whitby give this incidence as 3 per cent.

The question sometimes arises: Should the tonsils be enucleated first and the glands dissected out afterwards, or vice versa? In all cases in which it is possible it seems to me that the tonsils should be dealt with first and the original focus thus removed; but whenever the glands show signs of softening they should be dealt with first, thus making sure of a good scar in the neck; for, as you well know, it sometimes happens that directly after enucleation of septic tonsils, the neck glands break down or suppurate.

3. Recurrent sore throats due to frequent attacks of tonsillar inflammation or peritonsillar abscess.

4. Systemic infections attributable to a *focus in the tonsil*, such as rheumatism, irritable hearts, chronic ill health, and occasionally a rare toxaemia, such as that of the labyrinth.

5. Chronic lacunar tonsillitis, or "cheesy" collections in the supratonsillar fossa or between the tonsil and the pillars. These give rise to foul breath, a bad taste in the mouth, and pharyngeal irritation. This latter condition sometimes produces persistent fits of paroxysmal coughing.

6. In diphtheria "carriers" when the infection is persistent. These cases have not been common in my experience, but I have enucleated tonsils on at least three occasions when positive swabs had been returned for some months after the original infection, in each case with satisfactory results.

Diagnosis of Septic Tonsils.

And now as regards the diagnosis of chronic sepsis in the tonsils. The first point to mark is that the size of a tonsil is no guide to its septicity; indeed, small tonsils are often the worst offenders. It is often difficult to decide whether a given tonsil is really septic, and not infrequently the clinical signs are meagre.

The tonsil should be squeezed by pressing against the anterior faucial pillar with the end of a tongue depressor, so as to force out the contents of the crypts. Pus is sometimes made evident by this means. The anterior pillar of the fauces should be pulled forward with a blunt hook and the supratonsillar fossa examined by the same means. Cheesy secretions may thus be discovered. The tonsillar glands in the neck at the angle of the jaw should always be searched for, and frequently will be found. Chevalier Jackson and Davy-Smith have called attention to the presence of a narrow vertical red line of congestion, occupying, and limited to, the anterior surface of the entire length of the anterior faucial pillar. They have found this to be an important and distinguishing feature of a focal streptococcal infection. My own experience confirms this view.

Recently much work has been done on the tonsil puncture method of investigation, but of this I have little experience. The method promises to be useful in certain cases as a help in diagnosis, but my personal preference is always for a diagnosis on clinical grounds if possible. In those cases in which positive clinical signs of tonsillar sepsis may be doubtful and yet a definite condition due to focal infection, such as rheumatism, irritable heart, etc., is present, it is my practice to operate, after trying to eliminate all other possible foci, such as dental, nasal, etc.

Before leaving this part of the subject there is just one other point to consider. Many, indeed I think most, throat surgeons advocate the removal of tonsils as a routine measure in all cases in which an operation for the removal of adenoids is to be performed. This I do not quite agree with. It is true that in the great majority of such cases the tonsils are definitely diseased, or at least suspicious; but there remain a certain number in which, while the adenoids are causing definite symptoms, none can be attributable to the tonsils, and these bodies themselves present a perfectly innocent appearance—for example, cases of aural disease due to adenoids in which the tonsils are small, healthy-looking, and causing no symptoms. In such cases I remove the adenoids alone, for if the tonsils are not diseased we must presume, in the light of present knowledge, that they subserve a useful function, at any rate in childhood.

Tonsillectomy.

We now come to the operation of tonsillectomy, or the total enucleation of the tonsil in its capsule. Two methods are in use: (1) by means of the guillotine; (2) by dissection.

The method of dissection was popularized in this country by Waugh in 1909, and for a few years he had many ardent followers, but at the present time I would say that the majority of laryngologists prefer the guillotine, at any rate for routine cases. Personally, I am quite convinced that the guillotine method, in expert hands, is the safest, being, as a rule, a much shorter operation, and it is equally efficient. Moreover, more cases can be dealt with in a given time. As performed by many of its advocates the dissection operation requires a degree of anaesthesia so profound that it cannot be free from anxiety, and in some cases in which the operator also believes in ligaturing every bleeding point a very considerable period of time may be taken. This at once places the operation as a major instead of a minor one as regards risk. I am also quite sure that the ultimate results of the dissection method are no better than those of the guillotine. In efficient hands complete enucleation can be accomplished by either method and the result will be the same. In inefficient hands both methods may result in failure. Again, both the efficient guillotinist and the efficient dissector will occasionally have an imperfect result, as I have observed, not only in cases of my own, but in those of my colleagues in this and other towns.

Briefly, the case for the guillotine may be stated as an efficient removal of tonsils by a simple, short operation, entailing less risk, less discomfort, and a shorter convalescence than does the dissection method. The type of guillotine used is a matter of personal choice. Heath's is my fancy, and just recently I have tried the Popper-Heath modification with every satisfaction, the serrated portion of the inner ring margin of the head effectively anchoring the tonsil. Others prefer the scissor-handled O'Malley or Ballinger, and of late the crushing instrument of La Force has produced warm advocates.

The main contention of La Force is that the operation is rendered nearly bloodless in the majority of cases, but

there is, of course, no guarantee that both late primary and secondary haemorrhages may not follow its use. Macnab states that after a considerable experience of this instrument both primary and secondary haemorrhages were more frequent than with the single-bladed instrument, and others have also discarded its use after a fair trial. My own view is that it is not nearly so precise or efficient an instrument to manipulate, and that in the vast majority of my own cases I find little difficulty in confining haemorrhage to a minimum. In those cases in which haemorrhage is really troublesome it is very questionable whether a crushing instrument would be of help.

The dissection operation is now reserved by most laryngologists for special cases in which enucleation by the guillotine may seem to present difficulties, but I venture to say that the more one uses the guillotine, and the more expert one becomes, the less does one dissect.

Haemorrhage.

Bleeding is brisk for thirty to sixty seconds, but usually ceases spontaneously if the patient's neck and face are freely bathed in cold water. If this does not suffice, pressure should be applied to the tonsil bed for a minute or two by means of a swab on a holder, and if in three or four minutes bleeding is still free a swab squeezed out of hydrogen peroxide should be applied and pressure maintained for a further few minutes. In the vast majority of cases this will suffice, but in a few (about 1/2 per cent.) further pressure with a swab squeezed out of adrenaline will be needed, at the same time haemoplastin being given subcutaneously.

Beyond this I have had to go on only four occasions. Twice I have ligated a refractory artery of unusual size, situated in both cases at the upper pole of the tonsil bed, and twice I have left pressure forceps on the bleeding point for two or three hours after operation. Some laryngologists advocate the ligature of all bleeding points at every operation. This is a tedious business and considerably lengthens the time of the operation; moreover, it is not an infallible method of stopping haemorrhage, as ligatures have been known to slip, with subsequent severe haemorrhage after the surgeon has left. Many ingenious instruments have been invented for suturing together the pillars of the fauces in cases of severe haemorrhage. It is not a method which appeals to me, and I have never come across a case requiring such drastic treatment.

The surgeon may be called upon to deal with haemorrhage, more or less severe, a few hours after operation. In those cases the tonsil bed is filled with a large clot under which bleeding is taking place. After clearing away the clot, pressure, with the help of hydrogen peroxide or adrenaline, and the hypodermic administration of haemoplastin, has, in my experience, always been effectual in stopping it.

Fatalities.

I have operated on well over 12,000 cases of adenoids and tonsils with two fatalities. These cases, due to post-operative haemorrhage after the removal of adenoids, I have already referred to.

In the records of the Royal Manchester Children's Hospital for the last sixteen years—that is, the period during which I have been on the staff—I can only find a further three deaths following this operation. One patient died from the effects of post-operative haemorrhage, one from tuberculous meningitis. Neither of these cases did I personally see. The third died from sepsis after being operated upon by a medical officer at the out-patient department. A fourth case in which death might possibly be attributed to the operation was that of a mentally defective child at the Children's Hospital. This child, seemingly perfectly fit in every way, collapsed suddenly and died from heart failure three days after operation. A history of diphtheria some two or three months previously was elicited. So that in a period of sixteen years, 1913-28, there was a total of five, or at most six, fatalities following the operation for tonsils and adenoids at the Royal Manchester Children's Hospital. During this period over 27,000 such operations were performed.

As to the ultimate results of the operation I have no figures of my own to give.

In general terms it may be said that if the tonsils are efficiently enucleated the results, as regards the indications for operation I have enumerated, with the exception of chronic enlargement of cervical glands and systemic infections, are excellent, the condition being cured in nearly 100 per cent. of cases. In those cases in which a cure is not obtained it will be found that tonsillar tissue has been left behind.

MATERNAL MORTALITY.*

BY

J. PARLANE KINLOCH, M.D., M.R.C.P.ED.,

CHIEF MEDICAL OFFICER, DEPARTMENT OF HEALTH FOR SCOTLAND.

DURING the year 1928 there were 676 maternal deaths in Scotland, representing a rate of 7 per 1,000 births, as compared with an average of 6.4 for the preceding ten years. Of these 676 deaths, 234, or 2.4 per 1,000 births, were ascribed to puerperal sepsis.

A preliminary basis for the discussion on maternal mortality may conveniently be found in the conclusions arrived at from the special investigation into a total of 252 maternal deaths occurring in Aberdeen (1928) during the ten years 1918-27—namely:

1. The analysis of the records of maternal deaths in Aberdeen over a period of ten years, as obtained by means of a special system of inquiry, has not revealed any definite relationship between environmental conditions and puerperal mortality. Thus, in turn, puerperal mortality in relation to cleanliness of house, size of house, crowdedness of house, and to congested areas, has been examined, and no significant association of any of these conditions with puerperal mortality has been ascertained.

2. Similarly, the influence on maternal mortality of more personal factors, such as age of the mother, illegitimacy, occupation of the mother, habits of the mother, health of the mother before and during pregnancy, stillbirths and syphilis, and sequence of pregnancies, has been examined, with results that confirm generally existing views as to the influence of these various factors on maternal mortality.

3. The comparative maternal death rates from all causes and for the separate causes of death in the practices of doctor, midwife, district, and institution have been analysed, the factor of selection being eliminated by transferring the case back to the original doctor or midwife in charge of the case, and it has been found that the death rate per 1,000 maternity cases is 2.8 in the practice of midwives, 6.9 in the practice of doctors, and 14.9 in in-patient institutional practice.

4. The evidence indicates that, in so far as midwife cases are concerned, the application of midwifery forceps has no prejudicial effect on the mother.

5. Statistical evidence has been obtained of the reduction in maternal mortality which accrues from the provision of ante-natal services.

6. There is reason to believe that the high incidence of puerperal sepsis in maternity institutions in Aberdeen is due to contagion.

7. The view is advanced that the higher incidence of puerperal sepsis in the practice of doctors as contrasted with that of midwives is also due to contagion, being dependent in considerable part on a streptococcal carrier condition in doctors.

8. It has been shown conclusively that the *Streptococcus haemolyticus* plays by far the most important part in the causation of puerperal sepsis.

9. It has again been demonstrated that the same type of haemolytic streptococcus can on occasion produce puerperal fever, scarlet fever, erysipelas, and pyogenic infections.

10. The evidence goes to show that an expansion and improvement of ante-natal services will result in an important reduction in maternal mortality.

11. The evidence supports the view that the development of a new midwifery organization in which midwives conduct all normal deliveries, and in which doctors provide the ante-natal services and deal with obstetrical complications, will result in a significant reduction in puerperal mortality.

12. It has been shown that if the risk of contagion in maternity hospitals is to be restricted, then the number of patients and their spacing in the wards must be rigorously controlled.

* The opening paper of a discussion in the Section of Public Health at the Annual Meeting of the British Medical Association, Manchester, 1929.

13. So far as the specific prophylaxis of puerperal fever is concerned, it has been shown that while the exotoxins of the streptococci causing puerperal sepsis can be neutralized by any monovalent streptococcal antitoxin, the destruction of the organisms is only likely to be secured by the production of a type (serological) specific antibacterial serum.

Prevention.

The thesis is submitted, therefore, that in so far as the prevention of maternal mortality is concerned, and within the limits of our present knowledge, a significant reduction in maternal mortality would be immediately attained by (*a*) an extension of adequate ante-natal services, and (*b*) the institution of a new midwife-doctor combination as above defined (paragraph 11).

Diagnosis.

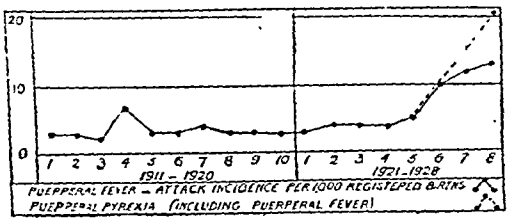
With reference to the bacteriological diagnosis of puerperal fever, confusion has resulted from the wealth of bacteriological data relating to the complexity of the flora of the genital tract (1928). It is admitted that there is a great variety of organisms in the genital tract at the time of the puerperium, and that puerperal sepsis is not necessarily associated with streptococcal infection. The point that matters, however, is that the serious forms of puerperal sepsis, and certainly some 90 per cent. of the deaths from sepsis, are due to infection with haemolytic streptococci. If serious morbidity and death from puerperal sepsis is to be countered, therefore, the essential is to concentrate on the haemolytic streptococcus.

Treatment.

Prevention and treatment cannot properly be considered separately, since adequate ante-natal treatment prevents maternal deaths in general, and since the early treatment of puerperal sepsis involves isolation and the prevention of further cases of sepsis by contagion.

In so far as treatment may lead to the prevention of serious morbidity and mortality from sepsis, the first essential is early recognition of the infection, and to this end puerperal pyrexia has been made notifiable in England, and is in process of being made notifiable in Scotland. Up to the present time the vast mass of cases of puerperal fever receive comprehensive treatment only when the disease is so advanced that the prospect of recovery is remote.

In this connexion the advantages of the notification of puerperal pyrexia can be seen from the following chart, wherein the figures of pyrexia notifications have been analysed and those attributable to sepsis added to the puerperal fever notifications.



The chart shows that during the four years 1925-28, during which pyrexia has been notifiable, the elicited incidence of puerperal fever has increased from an average of 3 per 1,000 births prior to 1925 to 12 per 1,000 births in 1928. It will generally be conceded that such increasingly early diagnosis of puerperal sepsis is bound to have a profound effect on the efficacy of treatment. From the clinical point of view the valuable results obtained by Remington Hobbs (1927) with reference to glycerin drainage of the uterus are noted.

A MODIFICATION OF LAGRANGE'S OPERATION.*

BY

W. H. KIEP, M.B., Ch.B.Glas.,

HONORARY OPHTHALMIC SURGEON, ROYAL EYE AND EAR HOSPITAL, BRADFORD.

Fifteen years ago, at the historical meeting of the British Medical Association in Aberdeen, it was my privilege to see a very interesting specimen, shown by Mr. Hill Griffith, of an eye that had been excised on account of late infection following trephining by Elliot's method. The details of that case are to be found in the *Journal* of the Association (1914, vol. ii, p. 389). They left a rather profound impression on my mind. Here was a perfectly good operation—and, after all, no fistulization operation has found greater favour with the ophthalmological world than has Elliot's—performed by a perfectly good operator, and yet it was followed by late infection that necessitated removal of the eyeball. In those days I was not in a position to do any operations for glaucoma on the living human subject, but when, a few years later, my opportunity occurred, it struck me that, after all, it was not so surprising that late infection should occur in cases of corneo-scleral trephining, because the membranous covering of the fistula must essentially be rather tenuous and flimsy if that fistula be situated at the corneo-scleral margin. Obviously, therefore, a fistulization operation, to be reasonably safeguarded against late infection, must provide for a membranous covering in the region of the fistula sufficiently thick and impermeable by micro-organisms or their toxins to prevent the occurrence of an iritis, or at any rate of a septic irido-cyclitis. Now I should like to state at the outset that it is not my intention to criticize Elliot's operation for glaucoma, nor yet to describe a new operation for that disease. Most ophthalmologists are conversant with all the operative procedures for glaucoma (and their number is legion), and have had successful results with any or all of them. The methods of Young, Holth, Herbert, Heine, Bentzen, and others have been described elsewhere, and have found, no doubt, their staunch adherents. I merely desire to describe a modification of an operation advocated by one of the greatest protagonists of sclerectomy—namely, Lagrange—which seems to me easier to perform than the operation he describes, and to yield results quite as successful as those which he claims.

Every ophthalmologist knows well the procedure of Lagrange's operation for glaucoma. Those who were present at the Oxford Ophthalmological Congress of 1927 listened with rapt attention to his address and never doubted his statement that "we have never seen late infection." The only drawback to his operation is the technical difficulty of its performance. Whitehead of Leeds alludes to this in his contribution to the discussion on the results of operative treatment of glaucoma. Besides, it will surely be conceded that the size of the scleral wound which Lagrange employed is out of all proportion to the needs of the case. As many other operators have shown, a sufficient piece of sclera can be excised from the lip of a wound made with a small keratome and the trauma to the scleral envelope correspondingly diminished.

The modification of the operation which I beg to submit is as follows:

Conjunctiva and subconjunctival tissue are grasped with forceps at a point 6 or 7 mm. above the limbus, and divided with straight-pointed scissors. The capsule of Tenon, if prolonged as far forward as this, should be divided likewise in order to secure the thickest possible covering for the fistulous track. This composite sheet of tissue, composed of the three layers named, is then cut with the scissors by means of a curved incision running concentrically with the limbus (more or less as in Elliot's operation), the total length of this incision being about 1.5 or 2 cm. It is then reflected downwards in the direction of the limbus by easy dissection until we get to within 1.5 or 2 mm. distance of the corneo-scleral margin, when the scissors are laid down. The flap should not be grasped by forceps, but simply kept out of the way by

* A paper read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Manchester, 1929.

means of moist cotton-wool swabs. A Took's corneal-splitting knife should then be taken, and with it a groove cut in between the layers of the scleral substance itself at a distance of 2 to 2.5 mm. from the limbus. It is neither necessary nor advisable to cut deeply with this splitter, but merely enough to make a small furrow running parallel with the limbus (corresponding to that between finger and a closely pared nail). Into this furrow a keratome is inserted and pushed downwards into the anterior chamber in much the same way as Heine does in his operation of cyclo-dialysis, except that the incision should be about 3 or even 4 mm. from end to end. The keratome should then be withdrawn as rapidly as possible. If this is done with sufficient speed very little aqueous is lost. The anterior lip of the scleral wound can now easily be gripped with Elliot's disc forceps and a small piece exsected (like the paring of a finger-nail) by means of de Weckers's scissors. By this time very probably a small portion of the iris, close to its root, has prolapsed into the wound, and this is excised, a strictly peripheral iridectomy being aimed at. If the operator has been successful in his efforts thus far he will have lost little aqueous and still have an uncollapsed anterior chamber. He should then gently stroke the conjunctival flap upwards, and by gently pressing on the corneal surface of the limbus in the region of the iridectomy with a spatula he can cause the whole iris to resume its normal relationships, excepting only for the peripheral iridectomy. The conjunctival flap is then secured with one stitch. Should the iris not have prolapsed of its own accord, then its periphery should be gently withdrawn with iris forceps and a pinhole iridectomy performed. In this case more aqueous will undoubtedly be lost, but it should still be possible to complete the operation without causing complete collapse of the anterior chamber. If the iridectomy is a purely peripheral one there should be no necessity to poke an iris repositor into the wound, with consequent increase in the loss of aqueous, as the iris can practically always be caused to resume its proper position in the way indicated above—namely, by stroking the *surface* of the limbus and adjoining cornea with a spatula in the region of the iridectomy.

I am not so foolish as to claim that this operation is unattended by drawbacks. Chief amongst these is that, seeing the episcleral tissues are cut right down to the substance of the sclera itself and then stripped off this membrane, episcleral vessels, sometimes of relatively considerable size, are almost certain to be severed, and may cause troublesome bleeding. They can, however, be picked up with fine (toothed) conjunctival forceps and the haemorrhage stopped by torsion of the proximal end of the vessel.

In other respects, I have found this operation no more difficult and not more frequently attended by complications in the performance than is Elliot's, and it is less "tricky" and demands less skill in its execution than does Lagrange's. The advantages I claim for it are, roughly, as follows.

1. It is possible to do this operation with the minimum disturbance of the intraocular structures and the minimum risk of intraocular haemorrhage. Cases of acute or congestive glaucoma with shallow anterior chamber should be treated beforehand with myotics and Duke-Elder's method of administering hypertonic saline intravenously. The operation can then, say a week later, be performed as on an uninflamed eye.

2. In a large proportion of cases it is possible to do the operation without causing the anterior chamber to collapse completely. The valve-like nature of the fistula (as opposed to the rigid circular foramen obtained by trephining) is of great assistance in this respect. The advantages of maintaining a sufficient depth of aqueous fluid between the cornea on the one side and the iris and lens on the other need not be stressed here, because they are sufficiently obvious to any operator of experience. But I may say that restoration of the anterior chamber to its normal depth follows, on the average, in from forty-eight to seventy-two hours.

3. The thickness of the membranous covering of the fistula is a more efficient safeguard against late infection than it is possible to secure in cases of corneo-scleral trephining, because in the latter operation little more than conjunctiva *per se* covers the fistula, whereas, in the operation I have described, the fistulous track is covered by conjunctiva, subconjunctival tissue, and Tenon's capsule. The fistulous orifice, moreover, is situated not at the corneo-scleral margin, but at a distance of 2 mm. or even more from it. That the protection from late infection is efficient, I have, in my own mind, little doubt. One of my cases, with very free filtration, had the misfortune to develop an attack of acute diplo-bacillary conjunctivitis about six months after operation. This attack passed off without being followed by any sign of iris irritation whatsoever (as observed with the slit-lamp, etc.).

4. Should, for any reason, a fibrosis ensue on this operation (as indeed may follow on any form of sclerectomy), a repetition of the operation may be performed without detriment. I have performed the operation successfully, and without difficulty, in a case in which a wide iridectomy had already been done for glaucoma, with insufficient results in the long run. A larger piece of sclera will, of course, have to be excised, but the previous history of the case will guide one in this respect.

In conclusion, I may perhaps be permitted to refer to a case in which this oper[illegible]ith other methods, was followed by

A married woman, aged 56, was seen by me in consultation with her medical attendant on the afternoon of March 14th, 1929. The presence of acute glaucoma in both eyes had already been diagnosed by her doctor, and the vision in the better eye (the left one) was no better than perception of hand movements, whilst that in the other eye was bare perception of light. She was admitted to the Eye and Ear Hospital, Bradford, a few hours later, and drops containing eserine 1 per cent., pilocarpine 2 per cent., and dionine 5 per cent. were instilled half-hourly, and, some five hours after I first saw her, 30 c.cm. of 30 per cent. aqueous solution of sodium chloride were administered intravenously according to the method of Duke-Elder. Next day the pupils were pin-point, and the patient was able to distinguish people at her bedside with her better eye, although the vision of the worse one (the right) was barely improved. Three days later the fields were, with a 5 mm. test object, as charted, and the vision of the right eye had improved to 6/60, and that of the left eye to 6/9. On March 21st the operation I have described was performed on the left eye, and on March 29th the patient was discharged from hospital, as she wanted to get home before her right eye was operated on. On April 17th she was readmitted to hospital, and the next day the right eye was operated on in the manner I have described. On May 11th the fields were, with a 5 mm. test object, as charted, and

V.R. with $-4\bigcirc -0.5 \downarrow 90°$ equalled 6/18;
V.L. with $-0.5 \downarrow 90°$ equalled 6/6.

ACUTE INTESTINAL OBSTRUCTION.

BY

H. W. L. MOLESWORTH, F.R.C.S.,

ASSISTANT SURGEON, ROYAL VICTORIA HOSPITAL, FOLKESTONE.

IN presenting for publication a review of 130 cases of intestinal obstruction which have been operated on by me, it is fitting that I should acknowledge the courteously given permission to make use of cases which I operated on whilst acting as surgical registrar to Sir Hugh Rigby, Mr. James Sherren, Mr. Russell Howard, Mr. Hugh Lett, Mr. A. J. Walton, Mr. Robert Milne, Mr. H. S. Souttar, Mr. E. C. Lindsay, Mr. W. S. Perrin, and Mr. G. E. Nelgan, all of the surgical staff of the London Hospital.

Surgical lectures and papers on the subject frequently end on a wailing note, as though the summit of knowledge and of technique had been achieved. It is suggested that the existing high mortality is all due to late diagnosis, and that the technique of treatment had reached finality. With this generalized conclusion we venture to disagree. As surgeons it is absurd for us to ask that all our work should be easy child's play. When we are still ignorant of so important a subject as the nature of toxaemia in obstruction it is presumption to assume that the technique of treatment is final. No one who has seen much of intestinal obstruction can fail to be impressed with the fact that some of the most desperate cases survive whilst some apparently trivial cases die. In the former it would seem that by a happy chance appropriate measures were taken, and in the latter that over-confidence led to the omission of some such measure as intestinal drainage, which may be called for as an afterthought in less timely circumstances than at the primary intervention. The cases reviewed are consecutive, and it has not been the practice to refuse operation to any patient who was not actually moribund. No patient who was refused operation lived more than two hours.

It is apparent that the comparatively low mortality in external hernia may be justly attributed to the ease with

which diagnosis is made. It is also probable that the propinquity of low intestinal coils to the usual hernial orifices, more particularly when the right side is involved, makes low obstruction likely, and means a later onset of the

	Cases.	Died.	Mortality per cent.
Strangulated external hernia	57	6	10 4
Obstruction to small intestine by adhesions, bands, foreign bodies, internal hernia, etc.	30	8	27 0
Intus-susception	20	6	30 0
Carcinoma of large bowel	20	6	30.0
Volvulus of large bowel	3	2	66 6
Total	130	28	21 5

toxaemia.[1] Twenty-three were cases of inguinal hernia, of which 3 died; 25 were femoral, with 2 deaths; and 9 were umbilical, with 1 death.

Of this group of cases, 8 demanded measures to deal with damaged bowel. In one case infolding of the damaged area was possible. In another, a two-stage resection of small intestine was successfully borne, and in 6 cases immediate resection and anastomosis was done; of these 5 died. This high mortality was, in our opinion, due to over-conservative resections, and to a failure at the outset to appreciate the need for intestinal drainage when resections of obstructed intestine were done. Of the 49 cases in which gut was deemed to be viable, one died.

The 30 cases of small intestine obstruction show 8 deaths. The series of cases shows a very marked improvement in results since two modifications in technique were adopted—spinal anaesthesia with neocain, and the addition of a jejunostomy in all cases where distension was extreme, or in which vomiting was a marked feature. At about the time that these measures were adopted greater emphasis on the need for saline administration was also made, and it is possible that this has played an important part. Before the change 18 cases included 7 deaths; since it, 10 cases included one death, in a patient so ill that a jejunostomy alone was attempted.

Twenty-two cases of large gut carcinoma are included; of these, 10 were situated in the sigmoid region, and 6 of these were operable growths. The practice has been to do a laparotomy under spinal anaesthesia; if the growth is operable caecostomy is done, and an attempt is made to resect the growth some ten days later. The "blind caecostomy" has not been done for the following reasons: (1) because a volvulus or strangulation is not likely to be benefited thereby; (2) because an inoperable growth will demand a more satisfactory permanent operation than a caecostomy can ever prove. The caecostomy is always made with a one-third to a one-half inch rubber tube inserted in just the same way as is a tube in the Senn gastrostomy. It has always closed spontaneously when the tube is removed. Usually there is no leakage at all.

Of these 6 operable cases, 5 have withstood the second stage of the operation successfully. One died of a pulmonary embolus the day before the second stage was to be done. In addition, one patient with carcinoma of the rectum was subsequently resected, and is now alive and well, eighteen months after the operation.

Twenty cases of intussusception have been treated; of these, a sausage-shaped tumour was palpable before the administration of an anaesthetic in 18, and in all 20 it was palpable under the anaesthetic. There have been 6 deaths. The average duration of operation for cases which did not need resection was twelve and a half minutes. Three cases were irreducible, and were resected: all three patients died, aged 4, 6, and 5 months. The remaining 3 deaths were due to (1) shock following a second operation for eventration; (2) shock in a baby of 7 months, in whom reduction had been extremely difficult; (3) an unexplained death, a week after operation, in a baby of 20 months, who had had a lax intussusception, which permitted the passage of some faeces, for 120 hours; reduction was so easy that operation took but seven minutes, and convalescence appeared to be normal until the morning of death.

Three cases of volvulus were treated; two were of the sigmoid about its base, one of the transverse and ascending colon about an axis formed by a long mesentery to the ascending colon, and aided by adhesion of the omentum to an abdominal scar. The latter patient recovered after untwisting and fixation of the colon. The two sigmoid cases died, one survived excision of the gangrenous loop with the insertion of Paul's tubes into the divided ends; three weeks later he developed small gut obstruction from adhesions, from which he died. The other died unexpectedly after the untwisting of a volvulus of a few hours' duration.

In addition to the above cases, two cases of enterospasm are mentioned, though not included in the statistics. Both simulated, and in fact were, cases of acute small gut obstruction. Both were explored under spinal anaesthesia, which, in these cases, did not at once relax the spasm. Both recovered.

Diagnosis of Intestinal Obstruction.

Intestinal obstruction being a symptom common to many pathological derangements, its diagnosis should rest upon the answer to a simple question. Certain volumes find their way into the intestinal lumen—namely, ingested food, fluids, and gases, *plus* fluids and gases which are poured into the lumen as glandular secretions and from the processes of fermentation. Healthy life demands that these volumes should leave the intestine at as great a rate as they enter. Some leave by being absorbed—for example, water, salts, nutriment. Others, faeces and gases, must be passed from the body.

The common teaching that the signs of obstruction include vomiting and absolute constipation passes over many serious cases of obstruction. The answer to the question, Is the intestine dealing adequately with its fluid content? implies a diagnosis between the absence or presence of obstruction. Failure to appreciate the fact that intestinal obstruction is consistent with the passage of some flatus and faeces leads to dangerous delays. Unless this fact is appreciated, the use of the diagnostic enema becomes a danger.

An illustrative parallel may be found in the diagnosis of retention of urine. It would be as accurate to state that a patient has no urinary obstruction because he has overflow incontinence as to claim that the passage of a small stool or of flatus negatived the diagnosis of obstruction. If the value of the trial enema is to benefit the patient its result must be measured by immediate improvement in all the signs and symptoms which have led to the suspicion of organic obstruction, and not, as is so frequently done at present, by an optimistic nurse's "good result."

Difficulties in the diagnosis of intestinal obstruction arise very infrequently when the cause is dramatic, as it is in volvulus, hernial strangulation, carcinoma, etc. They arise most frequently in patients recovering from peritonitis, from operations, and suffering from gall-stone ileus. We have found help in recalling that bands of adhesion firm enough to obstruct the intestine mechanically take some days to form. Distension and vomiting early in convalescence may justly be attributed to peritonitis or to internal hernia. After the fifth day they are probably due to bands of adhesions.

Anaesthesia.

General anaesthesia has special dangers in these cases. One mouthful of inspired vomit may readily seal the patient's fate, so that if general anaesthesia is to be employed passage of a stomach tube is an essential feature of the preparation for operation.

Spinal anaesthesia may be regarded as rather more dangerous than ether in ordinary cases. In obstruction the facilities that it grants to both patient and surgeon more than counterbalance its disadvantages. The relaxed abdominal wall, with the ease in exploration and suture which it gives, and the absence of the risk of aspiration of vomit, are advantages which directly benefit the patient. We are firmly convinced that the risk of spinal anaesthesia in intestinal obstruction is far less than that of inhalation anaesthesia of any kind.

The performance of caecostomy and of jejunostomy in obstructed patients is one of the questions in the surgery of intestinal obstruction which are still very much to the

fore. These two simple operations possess the common advantage that they relieve the obstruction. Another advantage which they possess is that they may be done under infiltration anaesthesia painlessly and with facility, and that an already poisoned patient is not submitted to the risks of a larger procedure, a narcotic drug, or the severe fall of blood pressure which is the occasional danger of spinal anaesthesia. In passing, we may remark that drugs such as strychnine, caffeine, and more recently ephedrine, do much to combat this fall. The disadvantage which is again common to both is that conditions endangering the vitality of a loop of gut cannot be benefited. A strangulation, a volvulus, an intussusception, or a Richter's hernia cannot always be diagnosed before operation. Jejunostomy is valuable in small intestine obstruction: first, as a method applicable in desperately ill patients, who will stand nothing more; secondly, and chiefly, as a supplement in all cases with severe distension. It is made with a catheter (No. 12), and, provided that it is infolded in the wall of the gut by the Witzel method, and also that the catheter is passed through a washer of omentum, it will close spontaneously when the catheter is withdrawn.

Help is given by the character of the peritoneal fluid. We have found that in every case of obstruction which we have explored peritoneal fluid is present to excess. In every case in which the vitality of a loop of gut within the abdomen was compromised this fluid has been blood-stained. If, then, in attempting a "blind caecostomy" or a "blind jejunostomy" the peritoneal fluid is bloody, it should act as a warning that exploration on a wider basis is imperative. It is probable that in strangulation of an internal hernia the blood-stained fluid will be found in the sac, and not free in the peritoneal cavity. This type of case will defeat the object of the "blind jejunostomy."

We may state that, so far, we practise spinal anaesthesia and a wide exploration as routine methods, reserving jejunostomy alone for the desperately ill, and as an adjuvant to the primary operation. Caecostomy alone is reserved for the obstruction whose site and nature and operability may be regarded as known. This narrows the field for "blind caecostomy" very considerably.

TOXAEMIA IN OBSTRUCTION.

It is sometimes assumed that all cases of intestinal obstruction exhibit well-marked toxaemia; this is rather far from being the fact. It is rare for a case of a large gut obstruction which is not associated with interference with the blood supply of a portion of intestine to show any evidence of toxaemia.[2] The majority of cases where there is obstruction in the lower reaches of the small intestine do not exhibit toxaemia until distension has reached the upper coils of intestine; or, in other words, the onset of regurgitant vomiting and of evidence of toxaemia are usually coincident. A clinical exception to this is that nearly all cases of strangulation of intestine exhibit toxaemia in disproportion to the degree to which the upper reaches of intestine are distended. On the clinical side it seems clear that toxaemia as a cause of death from obstruction does not enter into the picture until distension and vomiting have made their appearance; or in cases where there is a closed loop of intestine with interference with its blood supply. Amplifying this fact somewhat, the toxaemia, whatever it may be, depends on (1) high jejunal obstruction and distension, (2) a closed loop *plus* damage to mucosal blood supply. It is possible to have clinically a closed loop without interference with blood supply, and with no toxaemia, and, in fact, no serious symptoms. Serious symptoms will appear with the damage to the blood supply; but if the coil is low down in the small intestine toxaemia may not make its appearance.

The literature bearing on the cause of death in intestinal obstruction has become formidable in bulk and diverse in theory. It cannot be said that all the factors in obstruction are adequately explained by any of the theories which have hitherto been put forward. The following theories may be regarded as being seriously entertained at the present time:

1. That the phenomena in the toxaemia of intestinal obstruction are due to dehydration or to shock.[10]

2. (*a*) That toxaemia requires the presence of bacteria (the experimental work of Dragstedt and others). (*b*) The higher in the gut the more intense the toxaemia (Whipple and McQuarrie, Wilkie, and others). (*c*) That in addition to the appearance of bacteria some other factor which can be produced by damage to the blood supply is essential (Dragstedt, Moorhead, and others). It must be recalled in this connexion that the simple fact of intestinal distension of itself produces a congested condition of the mucosa which is sufficient to activate or liberate the toxin. Some observers working on different animals have found it difficult to show the appearance of toxaemia at all, and the degree of toxicity of intestinal contents appears to vary very greatly with the methods which are used to free it from bacteria (Wilkie).

3. That death is due to peritoneal infection. This theory has been widely held, and was at one time largely believed in by myself. It appears quite clear, in the light of the work of others, that the facts are against it as a constant factor in death from obstruction.

4. Liver and renal damage (McQuarrie and Whipple). It is undoubtedly proved that liver function and renal function are diminished in intestinal obstruction. The cause of their diminution remains unproved.

5. Anaerobic toxaemia theory.[7] It cannot be said that this theory explains all the facts. It has been shown that anaerobic bacteria are present in the intestine and are increased in obstruction. It is also a fact that they are present in the intestine of healthy persons. A similarity—not very striking—has been shown between the more extreme cases of intestinal obstruction and cases of gas gangrene; it may well be that death in all its guises wears much the same look.

This theory does not explain the fact that low intestinal obstruction may exhibit no evidence of toxaemia. Since the bacillus of Welch flourishes most in the lower ileum one would expect, if this theory is to be accepted, that the worst cases of toxaemia would be those in which a closed loop of lower ileum existed. The experimental work of Wilkie and of Dragstedt established the fact that lower ileal closed loops are compatible with prolonged good health. A case under my care existed for over a year in good health with a closed distended loop of lower ileum.

It is quite true that enthusiastic clinical reports on the treatment of intestinal obstruction with serum are received. It is unfortunately true that any new treatment is heralded with enthusiastic clinical reports, and it is only after some years that its true value may be assessed.

It has recently been shown[8] that intestinal obstruction is associated with a drop in the normal amount of chlorides in the blood, and that this drop commences to become steep with the onset of vomiting and the consequent loss of hydrochloric acid. Though the beneficial effect of the administration of saline has been known for years, the reason for its marked effect has not hitherto been so plausibly put forward. With the many theories that have been put forward, and the very large amount of experimental and clinical research into this subject, it is difficult to avoid the conclusion that the whole truth of this matter does not yet lie before us. It seems to be established that high intestinal obstruction is associated with virulent toxaemia. It seems also to be firmly established that chloride starvation exercises a marked effect on the patient's well-being, and it seems quite clear that the prevention of high intestinal distension by means of prompt surgical relief of the obstruction, and the use of high jejunostomy combined with the forced administration of hypertonic chloride solutions, as both pre-operative treatment and post-operative, are the chief measures which may be expected to lower the mortality.

IMPACTION OF SWALLOWED FOREIGN BODIES.

BY

HORACE MATHER, M.R.C.S., L.R.C.P.,

HONORARY OPHTHALMIC SURGEON, EYE AND EAR INFIRMARY, LIVERPOOL.

THE two following cases seem worthy of record on account of the remarkable history in each case.

CASE I.

On December 19th, 1928, a mother brought to hospital her baby, aged 3 weeks, saying that she thought the infant might have swallowed a safety-pin. On being questioned she stated that the day previously, while she was undressing the baby, which was on her knee, she dropped a safety-pin out of her own mouth, and failed to find it either in her own or the child's clothing. Suspecting that it had been swallowed she gave the baby a dose of castor oil, "to make sure," and put it to bed.

When seen, the baby appeared to be perfectly fit, but the resident decided to *x*-ray the child, and there was the open safety-pin, lodged in the œsophagus, with the point upwards, at the level of the manubrium sterni.

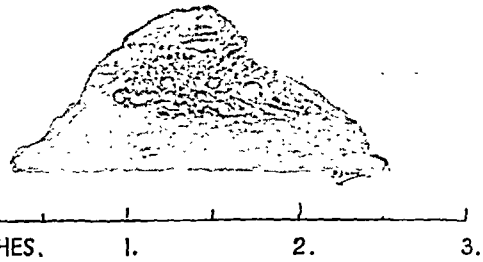
A few hours later I passed the smallest œsophageal tube that I had, under general anæsthesia, freed the impacted point of the safety-pin with Brüning's forceps, and removed it quite easily. It proved to be one of the gilt variety, measuring three-quarters of an inch from tip to bottom of hinge. The baby was perfectly fit, and was discharged a few days later.

In view of the extraordinary (in fact incredible) nature of the history, I interviewed the mother a week later, and questioned her. I felt convinced that I should elicit from her the fact that the pin had been sucked down by the baby, either from the mother's lips or fingers. I felt that no baby would swallow such an object, if dropped into its mouth when crying or yawning, for when feeding its mouth is practically closed. Also, why the dose of castor oil, unless the mother *knew* that the pin had gone down? However, I failed to shake her story, and was ultimately forced to believe her.

The second case was even more remarkable.

CASE II.

A man, aged 44, a factory worker, was admitted to hospital on December 31st, 1928; he was said to be suffering from tonsillitis.



He was treated for some days, and a note was made that his appetite was fair. He complained of a little pain in the throat and some difficulty in swallowing. He admitted that he could drink fluids, and on January 4th he ate bread-and-butter easily.

On January 9th he was sent to me with a request to look at his larynx. On doing so I saw a normal larynx, but above it a linear object. I asked him what he had been swallowing, and he denied that he had swallowed anything at all. I told him he had something there, and forthwith digitally removed a large bone (see illustration). The patient was as surprised as I was.

On going into the history I ascertained that on December 22nd (a Saturday night) he had had some soup, and felt abdominal pain after it. He was disinclined for food, and on Boxing Day he tried to vomit, and felt a sharp pain in his throat. I taxed him with being drunk on December 22nd, but he strenuously denied it, although he admitted that on that day, and on December 25th, he had had four pints of beer at most.

The bone measured 2¼ by 1 inch, and varied in thickness from 1/4 to 1/24 inch. It was wedge-shaped, and had been cut with a butcher's saw. It lay transversely in the pharynx, with the narrow edge upwards, impacted by its two "points," behind the epiglottis, and its thin edge lying upwards. It could only be seen from the mouth by means of a mirror.

My explanation of the case is that, in spite of his denial, he was drunk on December 22nd and swallowed the bone in the soup, and it went down sideways and lodged in the œsophagus, probably at the cardiac end. It was vomited up on December 26th, and lodged in the pharynx in its long axis. Being too drunk to know that it had gone down, he never suspected its presence when it returned. Consequently, neither he nor anyone else looked for it, and it was only by accident that I found it. Certainly it is remarkable that it should have been there for eighteen days.

MEDICAL, SURGICAL, OBSTETRICAL.

GRANULOMA INGUINALE RESEMBLING A PRIMARY CHANCRE.

THE following case is of interest since it shows how a disease rarely seen in this country may simulate and be mistaken for a common one.

A ship's steward, aged 30, developed a small papule on the glans four days after exposure to venereal infection in Brazil. This rapidly became an ulcer of about the size of a sixpence. After this ulcer had been present about six weeks the patient returned to England, where, *in spite of a negative Wassermann reaction and failure to find spironemes in the sore, a course of* antisyphilitic treatment was commenced. Eight intravenous injections of neokharsivan (total 4.5 grams) and eight intramuscular injections of bismuth metal (total 1.6 grams) had been given before the patient was seen by me.

The ulcer was still present, and apparently in its original condition, since it conformed with the original description: "punched-out, undermined edges, bleeds easily." The base of the ulcer was covered with healthy-looking granulations, scrapings from which contained numerous mononuclear leucocytes and also many bacilli showing bipolar characters with Leishman's stain. Many mononuclears were packed with these bacilli. There was apparently at no time any marked inguinal adenitis.

Treatment with antimony by the intravenous route was decided on. After the first injection of 0.3 gram of stibosan (von Heyden 471) the ulcer began to heal, and after five injections (total 1.5 grams), given on alternate days, the ulcer was completely epithelialized.

This case I believe to be one of granuloma inguinale in its early stage. The lesion was of small size, and the typical spreading condition involving the scrotum and inguinal regions, which, as Manson-Bahr points out, may take years to develop, was not present. The diagnosis, therefore, was not easy on clinical grounds, but is supported by the following points:

1. It was contracted in Brazil.
2. It was of three months' duration, and hence unlikely to be a chancre.
3. It showed no response to antisyphilitic treatment.
4. Scrapings showed intracellular bipolar bacilli.
5. The Wassermann reaction was negative six weeks after the sore first appeared and before any antisyphilitic treatment was given.
6. It healed rapidly on treatment with antimony.

It is important to remember the possibility of such a condition amongst seamen presenting themselves for treatment after arrival from foreign ports.

I am indebted to Mr. R. Stopford Taylor, D.S.O., F.R.C.S.Ed., for permission to record this case.

C. ALLAN BIRCH, M.D., M.M.S.A.

Royal Infirmary, Liverpool.

THE PLANTAR RESPONSE IN HYPOGLYCAEMIA.

IN view of Dr. D'Arcy Hart and Dr. Hilda Bond's article (May 18th, p. 895), the following case-history may be found of interest, bearing out as it does their finding that in hypoglycæmia the plantar response becomes extensor.

The patient, aged 21, was found, on admission to the Royal Chest Hospital, on June 8th, to be suffering from severe diabetes, his urine being loaded with sugar and acetone bodies, of which latter his breath smelled strongly. Treatment with insulin was therefore started at once, combined with a diet of 25 calories per kilo on Lawrence's low ration scheme. The insulin had to be increased till, on June 15th, he received no less than 120 units, but as he was sugar-free, the next day the dose was reduced to 80 units. Sugar reappeared in the evening, so on June 17th he was given 40 units before breakfast and 40 before lunch.

That morning he complained of pins and needles in his toes, but examination revealed no abnormality save a general weakness of muscular power. In the evening, however, definite hypoglycaemic symptoms arose. He could be roused only with difficulty, and spoke as if drunk. There was no sugar in the urine, and only a slight trace of acetone bodies. The knee-jerks were present as before, but the plantars were now definitely extensor. He was able to take sugar by the mouth, and so was restored to normal consciousness.

On June 18th he had 40 units before a two-line breakfast, and some six hours later he noticed a return of the premonitory symptoms. The knee-jerks were found to be brisk and the plantars still extensor. The administration of lunch put an end to the symptoms. On June 19th, on a reduced insulin dosage, he had no hypoglycaemic symptoms. The knee-jerks were now decidedly exaggerated, and he had developed ankle-clonus, but the plantars were no longer definitely extensor. On the following day examination of his nervous system revealed no abnormality.

As Drs. D'Arcy Hart and Bond only had the opportunity of observing two cases it has been thought worth while recounting this case fully. For though the precise moments at which the change took place were not ascertained, the fact remains that the plantar response, which was normal before and after the attack of hypoglycaemia, was extensor while it lasted, thus confirming what may come to be regarded as a useful clinical sign in the diagnosis of this condition.

I should like to express my thanks to Dr. A. W. Stott for permission to publish this case.

J. L. NEWMAN,
London, E.C.1. Resident Medical Officer, Royal Chest Hospital.

ARTERIO-VENOUS ANEURYSM FOLLOWING AMPUTATION.

THE following case seems of sufficient interest to merit publication.

An unmarried woman, aged 27, was admitted to hospital on April 5th last. Twenty-one years previously she had had amputation performed through the upper third of the left thigh, for sarcoma of the femur.

On examination a large multilocular pulsating swelling was seen occupying the whole of the old stump, the circumference of which was about twice that of the other thigh. On auscultation a continuous blowing systolic murmur was audible; there was also a soft blowing systolic murmur at the apex of the heart.

On May 15th an operation for ligature of the femoral vessels was undertaken by Mr. Harries, to whom I am much indebted for his permission and help in publishing this case. On exposure of the femoral vessels a distinct thrill was felt in the femoral vein, transmitted by the artery. The femoral artery was first tied; the thrill in the corresponding vein then disappeared, as also did the blowing systolic murmur at the apex of the heart. Finally, the vein also was tied. Clotting took place soon after operation, and the patient was discharged a fortnight later.

I have never read of a similar case, and can only assume that communication was somehow established between artery and vein, giving rise to the above condition.

DONALD W. STUART,
House-Surgeon, Cardiff Royal Infirmary.

MECKEL'S DIVERTICULUM IN AN INTUSSUSCEPTION.

THE case described below seems of sufficient interest to warrant publication.

On June 23rd Dr. F. E. Daniel sent in a boy, aged 18 months, with a provisional diagnosis of intussusception. The illness began at 10 a.m. When seen in the afternoon he was vomiting and collapsed. There was no blood in the rectum, but a mass could be felt on the right side of the abdomen. There was no rigidity.

At 4 p.m., assisted by Dr. Rutherford Bayne, I opened the abdomen and delivered the mass. It involved the caecum, part of which was invaginated. This was easily reduced, leaving about 1 foot of ileum entering the lower end of the ileum. Reduction was a simple matter till we came to the final nodule, which was found to consist of a completely inverted Meckel's diverticulum about 2½ inches long, the final inch of which could not be reduced. It was clamped and removed. The diverticulum was oedematous and nearly gangrenous, and had apparently been the apex of the intussusceptum. Several tuberculous glands were noticed in the mesentery. After removal the inversion of the diverticulum was reduced with considerable difficulty. The boy recovered.

JOHN LIVINGSTON, M.D.Durh., F.R.C.S.Ed.,
Honorary Surgeon, North London Hospital.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH.

DR. T. E. HINCKS, in delivering his valedictory address as president of the Worcestershire and Herefordshire Branch of the British Medical Association, chose as his subject his thirty years' experience of maternity practice in a rural district.

Rural Midwifery Practice.

He thought that the subject would interest, and possibly prove of some practical value to, his medical confreres, many of whom were men with experience gained in hospital and large town practices. At the present time aspersions on the general practitioner were made by men high in the profession who spoke from statistics, without a first-hand knowledge of facts. Doubtless the politician with the country's interest at heart could mitigate the difficulties that continually arose; but he should first see that a properly qualified midwife was available in all rural districts, without taxing the philanthropy of the few. Secondly, he should see that maternity wards existed in every hospital, with accommodation in proportion to the population.

The conditions of practice in Dr. Hincks's area had altered very materially for the better of late years. Until fifteen years ago most places were reached in gig or on horseback, and the doctor's armamentarium usually consisted of a pair of forceps shoved in his riding breeches pocket, a bottle of chloroform, and another of ergot. To-day the midwifery bag with its sterilizer weighed exactly 2 st. On one occasion Dr. Hincks was called to a case up in the hills, and being met on the road by the husband gave him the bag to carry one mile, with a steep gradient all the way. Coming back the man said, "Doctor, have I to carry this bag every time my wife has a baby?" "Yes, my friend." "Damn, then, there'll never be another." In former days there was not a single qualified midwife residing in the district. Even to-day in a great part of his practice in Herefordshire there was not a qualified maternity nurse available. But in Radnorshire, which was the most sparsely populated county and the most difficult of access in England and Wales, every district was supplied with a nurse working under a district nursing association, each being subsidized by a grant of £50 or more by the county council. There was, of course, much prejudice to be overcome against district nurses. Washing was objected to; soiled garments and sheets could not be changed lest the patient should catch cold; and, of course, old Mrs. Gamp did the household work while her patient was confined to bed. In those days the doctor acted as nurse, and Dr. Hincks attributed a lot of success in early days to his father's insistence on always washing the patient, and changing nightdress and sheets of every case before leaving the house. Many ignorant customs, however, still survived. Thus it occurred even now that on arriving at a house with the baby born, the cord was found attached by string to the leg of the patient; and frequently the patient's fingers were tied round with wool to prevent haemorrhage.

Going through his books of the last thirty years, Dr. Hincks had found records of 1,575 cases, and had classified these in three decades. Of cases seen in the first and second stages of labour, 822, or 52 per cent., were normal deliveries; 698, or 44 per cent., were forceps cases. In the first decade forceps cases amounted to 45 per cent.; in the second decade they fell to 39 per cent., and rose in the third decade to 48 per cent. In the early days, when there were no nurses, cars, or telephones, the doctor was often sent for too soon. He could not go home and run out again easily, and had to choose between quickly terminating labour and getting home, or tolerating the chafing impatience of the patient and her friends. He frequently resorted to the unnecessary use of forceps. The fall to 39 per cent. in the second decade could be accounted for by

the advent of motor cars. Having left instructions to be sent for when the membrane ruptured, he had returned to find the baby born, and only the clearing up to be done. The rise in the third decade to 48 per cent. was undoubtedly due to the district nurse, who dealt with the majority of cases, and only sent in those of prolonged or difficult labour, and, worse still, of post-partum haemorrhage or adherent placenta. Eleven cases of internal version, done in cases of shoulder and transverse presentation, called for no special comment, except one case in which spontaneous delivery occurred before his arrival. The operation of craniotomy was rarely required nowadays, because pre-natal examination was insisted on in all first cases. In one case up in the hills, where forceps failed to deliver an impacted head, perforation was done with a pair of cutting-out scissors.

Caesarean section had been used in nine cases. Seven of these were for uniformly small pelvis in primiparae. Two of them were patients in labour who had not previously been seen. The other two cases were rather interesting. One was a case of a soft tumour, an ovarian cyst, projecting in front of the head. Forceps were applied, but of course failed. The patient was promptly removed by car to Hereford, where Caesarean section was performed. The second was a multipara. On examination no signs of an os could be found, though she had been in labour for many hours. She was anaesthetized, and on introducing the hand into the vagina a partially dilated cervix could just be felt, pointed upwards and backwards towards the abdomen. Dr. Hincks suddenly remembered that this was a woman he had sent to Cardiff for operation for prolapsed uterus. She came back, and, as vaginal operation was unsuccessful, he sent her to a Birmingham surgeon, who did ventral fixation, and returned her with a note that "prolapse would never recur." It did not, but Dr. Hincks sent her into Hereford, and a successful Caesarean section was performed. All these four patients had been taken twenty miles by car into hospital after labour had started. In one case forceps had actually been applied. All the Caesarean sections, both mother and child, did well; and looking back over craniotomies and difficult forceps deliveries, resulting frequently in the death of the child, Dr. Hincks felt that had pre-natal examinations been regularly carried out many more Caesarean sections or induced labours at the eighth month would have been done. Instead of blaming the general practitioner for excessive maternal mortality, those in authority should direct their energies to establishing a maternity ward in Hereford General Hospital, thus doing something to lessen the risks of complicated cases of labour, and decreasing the subsequent morbidity of mothers.

Breech presentations, 28 in number, were 2 per cent. of the total cases. One unfortunate case occurred recently in a primipara, aged 33. Three weeks before labour she was examined. The measurements were 9½ in., 10½ in., and 8 in., but a breech presentation was discovered; it was decided to let the case take its natural course. Twelve hours after labour commenced the cervix was fully dilated, but the breech had not engaged. Under chloroform, with great difficulty owing to narrowness of the brim, a leg was brought down and the breech delivered, but there was absolute failure to get the head through. Eventually forceps were applied to the after-coming head, which, with the greatest difficulty, was delivered. The patient was two hours under an anaesthetic. The placenta came away normally, but the woman was suffering severely from shock, with a pulse of 140. She vomited black material immediately after recovering consciousness, and vomited persistently during the next four days; the pulse rate came down to 100, and the temperature was normal. On the fifth day she became unconscious, with rapid respiration. She died, probably from cerebral, and possibly pulmonary, embolism. Breech presentations, Dr. Hincks thought, were often due to some pelvic abnormality; in future he would always regard them with suspicion, and in a primipara with small pelvis would consider inducing premature labour or performing Caesarean section.

Dr. Hincks described two cases of puerperal eclampsia. A woman walked into his surgery, seven and a half months pregnant, with oedema of her legs, and a high degree of albuminuria. She was ordered to bed and given a saline purge. The following morning she had a fit. She became comatose, with continually recurring fits. The cervix was rapidly dilated and the uterus emptied, but she never regained consciousness and died a few hours later. In the second case the patient was having repeated convulsive seizures, and was comatose. She was brought down one and a half miles on a canvas stretcher to a car, and rushed into Hereford. Labour pains set in on the journey, and she was delivered with forceps shortly after arrival at hospital. The mother and infant did well. Dr. Hincks had records of only two complete cases of placenta praevia. One was treated by turning and bringing a leg down. This at once stopped the haemorrhage, which had been very severe. The other case ended disastrously. The patient was found pulseless from extreme haemorrhage. She had been in labour some hours, an arm was protruding, the pains were intense, and the shoulder was fixed in the pelvis. With the greatest difficulty the placenta was separated and the child turned; but in doing so the lower uterine segment was ruptured, being no doubt thinned out dangerously after so many hours of severe uterine contractions. The patient died four hours later. Six per cent. of the patients had retained and adherent placentas. Of these, 41 cases were accompanied with post-partum haemorrhage, but there was scarcely any haemorrhage in the remaining 60. It appeared that there was little or no haemorrhage with the completely adherent variety, but the partially adherent form bled freely, especially when accompanied by uterine inertia, as also did retained placentas with uterine inertia. Dr. Hincks was of opinion that, since the introduction of pituitrin, post-partum haemorrhage from uterine inertia could be practically eliminated. In the first decade, before pituitrin was used, his record showed 52 cases of post-partum haemorrhage—30 of these due to uterine inertia (5.5 per cent. of all the cases); in the last decade 12 (2.2 per cent. of all cases), and of these 10 occurred in cases in which the child was born before his arrival. Puerperal fever occurred in 26 cases, approximately 1.6 per cent. of the total; 10 of these followed the use of forceps, 1 internal version, 5 adherent placenta, and 10 were absolutely normal cases of labour in which there was no intervention at all. Two of these cases proved fatal. The total maternal mortality in Dr. Hincks's cases was 10, equivalent to 0.6 per cent. of the patients attended: ruptured uterus 2, puerperal fever 2, haemorrhage 2, syncope 2, coma following puerperal eclampsia 1, and thrombosis 1. Of the two deaths from ruptured uterus, that due to uterine tumour might have been averted by Caesarean section. The second due to placenta praevia—severe ante-partum haemorrhage and finally ruptured uterus caused by turning in an impacted shoulder case—was inevitable in anyone's hands. In the first case of death from haemorrhage the patient was found pulseless, suffering from severe ante-partum haemorrhage, due to partial placenta praevia. The midwife was drunk in a corner of the room, and had refused to send for medical aid, though repeatedly asked by the patient's friends to do so. Delivery with forceps failed, but was rapidly accomplished after perforating the child's head. The woman died within two hours from the result of ante-partum haemorrhage. In the second case the woman was dead on arrival owing to adherent placenta and post-partum haemorrhage. Her life had previously been saved on two occasions from the same complications. The first patient who died of syncope was always a delicate, anaemic woman. On arrival she was found collapsed and pulseless; there was a history of breech presentation and prolonged delivery. The placenta was expressed by hand. There was no haemorrhage. She died from shock two hours later. The other patient was an alcoholic who expired a few minutes after the easiest forceps delivery. These cases, and the death due to puerperal eclampsia and coma, were inevitable. The case of thrombosis after extremely difficult delivery might have been saved by Caesarean section or induced labour at the eighth month. The two cases of death from puerperal fever followed, in one instance, removal of an adherent placenta and profuse post-partum

haemorrhage, in the other a simple forceps delivery. So that of these ten deaths, six were inevitable, two could have been saved by Caesarean section, and two puerperal cases might, Dr. Hincks said, have cast a reflection on himself.

In concluding his address Dr. Hincks protested once more against men who were sitting on office stools perusing statistics, knowing nothing first-hand of the facts, and yet writing scathingly of the rural general practitioners and blaming them for a high rural maternal mortality. It was not the general practitioner's fault that rural maternal mortality was high. It was extraordinarily low, when one considered the difficulties under which the work was done.

Reviews.

MOVABLE KIDNEY.

A SECOND edition of *Movable Kidney*,[1] by Mr. WILLIAM BILLINGTON, has recently been published. The first edition appeared nineteen years ago, and the present one is slightly enlarged, with several new plates. The controversy that at one time raged round nephropexy has in large part died down; since the first edition there has been a great change in our attitude towards surgical diseases of the kidney, and the subject has passed into the hands of the specialist. At the present time it is fair to say that the number of nephropexies has greatly diminished, and that only in a few chosen cases is the operation performed. If, after the lapse of twenty years, some surgical procedure for which high claims have been made has not become widely established, it is reasonable to assume that the original claims for it have not been made good. Mr. Billington puts his case well and fairly, and if the reader should become too enthusiastic the last well-reasoned chapter will act as a corrective.

The book opens with an excellent chapter on the anatomy of the normal kidney, and another on the mechanism by which he considers the loose kidney to occur. He points out that there are two distinct types, one in which there is dropping of the organ, chiefly found in women, and the other in which there is rotation of the lower pole inwards, mainly to be found in men. The succeeding chapters are concerned with the etiology and pathology of the condition, with a chapter devoted to visceroptosis and nephroptosis, the author pointing out that in general visceroptosis nephropexy is inadvisable. In the section on pathology the inferences drawn in the paragraphs on the renal vessels and the renal nerves will not meet with agreement from every reader. There follows, after pathology, a chapter on diagnosis, and in this the importance of examining the patient in the upright position and on the side is rightly stressed. The author also appeals for better pyelograms to be taken with the patient standing. Two new plates are introduced showing pyelograms in the same patient, one taken while the patient is lying down and the other with the patient standing, illustrating the dropping of the kidney. A further series which showed the patient before operation and some time after would have been instructive. Four chapters on the symptoms produced by movable kidney then follow; these might have been interposed before the chapter on diagnosis.

In the treatment of the condition the use of belts is discussed, and dismissed except in the case of nephroptosis in association with visceroptosis. The treatment favoured is nephropexy, and the author describes his technique very clearly with the help of good diagrams. The last part of the book deals with the author's results. He has had an extensive experience, 1,500 cases in twenty-five years, and in a large number of these the double operation has been performed. Nephropexy without some other operation, chiefly appendicectomy, was performed in 12.6 per cent. of cases, and in assessing the end-results this has to be taken into consideration. An analysis of his cases and results by Professor Kaufmann is given.

[1] *Movable Kidney.* By William Billington, M.S.Lond., Ch.M Birm., F.R.C.S.Eng. Second edition. London: Cassell and Co., Ltd. 1929. (Demy 8vo, pp. ix + 177, 7 figures, 14 plates. 12s. 6d. net.)

BALNEOTHERAPY.

MANY practitioners throughout the country are frequently called upon to advise their patients as to the best type of spa for their particular malady; to tell them what exactly are the advantages of the spa selected; and, in these days of intelligent interest in the physiological effects of treatment, how the treatment is supposed to act. There are also a far larger number of patients who want to know whether a certain kind of spa treatment cannot be given in or near their own homes. The test of the value of any book on this subject is whether the answers to questions such as the foregoing can be found quickly, and, when found, whether the directions and statements are clear and accurate. It is in this way that Dr. MATTHEW RAY'S book *On Prescribing Physical Treatment*[2] has been tested again and again, and we find that questions such as "What are the baths employed in treating fibrositis?" and "What is the nature of the treatment at Nauheim?" are answered fully and clearly. Again, the instructions for giving such treatments as abdominal hot packs are simple, definite, and could be carried out by any practitioner with confidence. This method of dealing with the subject is useful, as baths, mud packs, and many other physical treatments would be utilized far more freely if the effects and technique of their application were more readily available.

Dr. Ray's book therefore fills a much-needed gap, and it should be close to the desk of the continually increasing number of doctors who look more and more to physical methods of treatment for their results. With the advent to London of a central clinic for rheumatic diseases, modelled on the lines of the best Continental ones, it is probable that a second edition will be required at an early date. When this is being prepared we hope that, even at the expense of some repetition, the paragraphs on therapeutic indications will be self-contained and not refer the reader back to some previous page. There is one strange omission from the index, which includes spas from Aachen to Woodhall Spa, and that is Bath—mother of all spas. Apart from this the book may be recommended as a valuable work of reference, and not too expensive, for use in much the same way as the *Materia Medica* of Hale-White, which has been used by generations of medical men.

DISEASES OF THE THYROID GLAND.

DR. A. E. HERTZLER has prepared an enlarged and more copiously illustrated edition of his monograph on *Diseases of the Thyroid Gland*,[3] whose first edition was favourably noticed in our issue of March 3rd, 1923. The work contains information derived from thirty years' experience in what Dr. Hertzler modestly calls a small country hospital, devoted almost exclusively to the study, treatment, and after-treatment of goitre patients; if, then, some of the conclusions and suggestions are a little heterodox, they have at least the merit of being based entirely on long and patient personal observation. The author's main contention is the unity of the conditions known as colloid goitre, non-toxic adenoma, toxic adenoma, and frank hyperthyroidism. He produces evidence that the activity of the interstitial cells of the gland is associated with a definite clinical type of thyroid intoxication. Treatment is very fully studied, with special reference to the indications for surgical treatment. Indeed, the writer goes so far as to say that the ameliorative effects of radiotherapy are mainly due to the urbane and persuasive manner of the "*x*-ray man." Apart from formal descriptions of symptomatology and etiology, the book contains long and valuable chapters on pathological anatomy and surgical technique. The former is abundantly illustrated by excellent photomicrographs, and the latter by new clear drawings. There is a special chapter by Dr. Victor Chesky devoted to the hospital management of goitre patients. The book is written primarily for surgeons, but the pathologist and

[2] *On Prescribing Physical Treatment.* By Matthew B. Ray, D.S.O., M.D.Ed. London: W. Heinemann (Medical Books) Ltd. 1929. (Demy 8vo, pp. ix + 174, illustrated. 10s. 6d. net.)

[3] *Diseases of the Thyroid Gland.* By A. E. Hertzler, M.D. Second edition. London: H. Kimpton. 1929. (Sup. roy. 8vo, pp. 286; 159 figures. 32s. net.)

physician will find much in it of interest and value. It is beautifully printed, and, notwithstanding certain crudities of expression, very readable.

In his monograph on the pathological foundations of the treatment of thyroid disorders[4] Professor HOLST of Oslo gives a survey of the biochemical disturbances in various goitrous diseases, with special reference to frank hypo- and hyper-thyroidism. The normal and abnormal metabolism of iodine and the place of iodine in therapy is very fully discussed. There is a long chapter on the surgical management of hyperthyroidism, and a full description of post-operative technique. The conclusions are fortified by a substantial mass of clinical data showing the relative places of iodine therapy and surgical treatment in a large number of patients. The volume is copiously illustrated with attractive diagrams and charts, and is furnished with a bibliography, which is, however, far from complete.

OLD MASTERPIECES IN SURGERY.

DR. ALFRED BROWN has done a useful piece of propaganda for the history of medicine by collecting and reissuing under the title of *Old Masterpieces in Surgery*[5] the articles he contributed to the *Journal of Surgery, Gynecology and Obstetrics* during the years 1924, 1925, 1926, and 1927. The busy doctor has not hitherto been greatly interested in the history of his profession. After a long day, and with the prospect of an interrupted night, he has been more inclined to read his newspaper or take down a detective novel than to turn to the more serious works of Freind, Garrison, or Charles Singer. The *Old Masterpieces of Surgery* should alter all this, for Dr. Brown has acted like the schoolmasters spoken of by Horace, who

> "pueris dant crustula blandi
> Doctores elementa velint ut discere prima"

(give cakes to their boys to wheedle them into learning the alphabet). He has written a series of slight articles and has illustrated them beautifully, so that those who read his book will soon fall in love with the subject and will desire to pursue it further. Indeed, there is evidence that medical history is already being more seriously studied in the United States than in Great Britain. The *Annals of Medical History* and *Medical Life* are entirely devoted to the subject and never lack interesting articles, whilst in this country there are no periodicals dealing exclusively with such history.

The articles written by Dr. Alfred Brown range from Soranus, who flourished A.D. 100, to Cheselden, surgeon to St. Thomas's Hospital, who died in 1752. They are for the most part accurate, though he repeats the fable that the school of Salerno was founded by a Jew, an Arab, a Greek, and a Roman, and believes Trotula to have been a real woman with a corporeal existence. He states, too, that Vicary wrote the *Englishman's Treasure*, though it is well known that Vicary's work is merely a transcript which he made and somewhat condensed from a manuscript written many years earlier. He gives valuable advice to his readers in the foreword when he tells them to study the prefaces to the old books on medicine and surgery, for "the author there comes into the most intimate contact with the reader and unburdens his soul, giving, in some instances, his object in writing the book and sometimes the circumstances under which it was written." For these reasons the prefaces are now often more valuable and interesting than the text.

At first sight it is somewhat surprising that the work should be published at Omaha, which is not generally associated with literary enterprise. A little reflection shows that it is largely due to the energy and public spirit of Dr. and Mrs. Le Roy Crummer, who have made a priceless collection of old medical manuscripts and books which they have generously allowed Dr. Alfred Brown to use. It is to be hoped that a second series of articles on similar lines will be issued, for as yet no American surgeon has been included, and there are many worthy of commemoration. When this is done it might be as well to add a note at the end of each article saying where more detailed information can be obtained. The Lakeside Press at Chicago is to be congratulated on the volume; the paper, printing, illustrations, and format generally are beyond reproach, with the result that the volume may be described as sumptuous.

GYNAECOLOGY AND OBSTETRICS IN THE TROPICS.

DR. GREEN-ARMYTAGE'S two small works on *Tropical Gynaecology*[6] and *Tropical Midwifery*[7] have been revised and brought up to date in a manner upon which the author is to be congratulated. In the form of bright, terse, clinical lectures these books allow the pleasant perusal of important detail, while they hammer home the essentials. Controversial subjects, when unavoidable, are fairly set forth in their several aspects, along with a definite expression of personal preference. This, from an author with such immense experience, gives the books real value, just as their style imparts real pleasure. We would have liked to see more evidence of a proof-reader's skill, for printer's errors are over-plentiful, especially with regard to type faults; and words like "mental massage" (p. 70) and "repone" (p. 92) in the volume on gynaecology look odd. Such minor flaws, however, cannot spoil the intrinsic worth of these books, both text and figures conveying an astonishing amount of information compressed into delightfully small compass.

HISTOPATHOLOGY OF THE MIDDLE EAR.

THE study of the histopathology of the ear has always presented such difficulties that it has been followed less widely than in most regions of the body. There is not only the difficulty of obtaining suitable pathological material, but the task of making sections of the temporal bone requires great expenditure of time and patience in addition to a profound knowledge of anatomy and of pathological technique. It has by no means been neglected, but has been necessarily confined to a few select investigators. *Les Otites Moyennes*,[8] by GEORGES PORTMANN and KARL KISTLER, consists chiefly of a number of excellent reproductions of microscopic preparations showing the pathological processes which occur in the middle ear. The authors think that the ideas and researches of Bezold have been neglected in France, and seek to confirm them. In this country they have long received recognition and acknowledgement in all important textbooks, so that the necessity for such a book would be less evident outside France. The authors, however, present their subject pictorially in a highly instructive manner, the main thesis being the overwhelming importance of cholesteatomatous formations in chronic aural suppuration. The literary output of Professor Portmann must exceed by far that of any of his contemporaries, and the text which surrounds these admirable illustrations shows signs of hasty compilation. The source of the illustrations is not clearly indicated, and there are no references to authors whose works are freely quoted. Such an admirable collection of pathological material deserves to have had more literary care expended upon it. The book should be useful at the beginning of a serious study of diseases of the ear, when a sound pathological knowledge should form the basis for clinical work.

EPILEPSY.

THERE must be few reviewers who would not confess to some heaviness of heart on taking up a new book upon epilepsy. One knows from long experience exactly what one will find. The historical introduction, with an allusion [illegible] the excellent clinical account of aura,

chapter in which every possible metabolic investigation will be impartially recorded; the speculations as to the cause of the attack, inhibition versus excitation, vascular spasm versus neural explosion—can there be any reader, one wonders, who does not by now know all this by heart? Dr. OTTO CROUZON'S book *Le Syndrome Epilepsie*[9] provides for the French medical profession a review of the state of our ignorance about epilepsy which is comparable with the volume recently produced by Dr. Stanley Cobb and Dr. Lennox in English. Following the French neurological tradition, Dr. Crouzon devotes more space to clinical features and to treatment and less to neurophysiology than the American authors. His book can be recommended as an excellent monograph in which all aspects of the subject are discussed with judgement and thoroughness.

NOTES ON BOOKS.

DR. HARRY L. ALEXANDER'S little book *Bronchial Asthma: its Diagnosis and Treatment*[10] contains a good review of the whole subject. In the chapter on the pathological findings some interesting original observations are recorded, the author having had the very unusual experience of attending three cases in which death occurred during an attack. The changes observed were most marked in bronchioles of 5 mm. diameter, and were absent or slight in those less than 2 mm. The epithelium, which contained unusually numerous and large goblet cells, was thrown into deep folds. The subepithelial layer was hyperaemic and infiltrated with lymphocytes and eosinophile cells, which also surrounded and even invaded some of the muscle fibres. The muscular coat was thickened, in part owing to persistent spasm and in part to liver hypertrophy. Some of the smallest bronchioles shared in the dilatation of the alveoli caused by the obstruction above. The price of the book (10s. 6d.) seems excessive, as it consists of only 171 small pages.

The fourth bimonthly number of the *Annals of Medical History*[11] contains nine articles, in addition to the extremely interesting editorial on Sir Christopher Wren, whose portrait forms the frontispiece, and the discriminating book reviews. Dr. E. Robert Wiese sets out the fine character and achievements of Baron D. J. Larrey (1766–1842), who was one of the few men who dared to contradict Napoleon, and one of the fewer still from whom Napoleon would brook opposition; apparently entirely devoid of fear, he was self-reliant without self-assertion. His handsome features adorn the cover of this number. In his account of Charles Edward Isaac (1811–1860) as a forgotten American kidney physiologist, Dr. R. E. Bieter pleads that his name should be added to those of his two contemporaries, Bowman and Ludwig, to make up a great triumvirate in renal physiology. In a study of epilepsy in the light of history Dr. E. H. Pirkner discusses the evidence of this disease in a number of distinguished characters, such as Julius Caesar, Mahomet, King Saul, St. Paul, Dostoievsky, Flaubert, and Napoleon. Dr. J. L. Miller dwells on the diseases of ancient times, and particularly with those of Egypt. Dr. Joseph Walsh, in an article on the date of Galen's birth, suggests that a centenary commemoration might be held on September 22nd, 1930. Dr. R. L. Pitfield writes with affection of Lamb, whom Thackeray called "Saint Charles," and entitles his article "A pitiful, rickety, gasping, staggering, stuttering Tomfool," the venomous words of Thomas Carlyle about the author of *Elia*. A number of extracts from the notebook of Edward Jenner are reproduced by Dr. Le Roy Crummer. In reminiscences from the early days of the Pennsylvania Hospital Dr. E. A. Strecker points out that, as it was opened in 1752 for the care of the insane, it is the cradle of American psychiatry. In a brief note on medical philately Lieut.-Colonel Fielding Garrison mentions that the first medical men's portraits to appear on postage stamps were those of military surgeons: Kaczkowski, surgeon-general of the Polish Army in 1831, appeared on Polish stamps in 1927, and Surgeon-General W. C. Gorgas on a recent issue of the Republic of Panama.

A new edition of the Catalogue of Lewis's Medical and Scientific Circulating Library, revised to the end of 1927, has been published.[12] Part I is a complete list of books available to subscribers, arranged alphabetically under the authors' names; each entry gives the size of the volume, its price, and the date of the edition. Part II is a classified index of subjects with the names of authors who have written upon them. A new feature of this index is the addition of many authors' initials to facilitate reference to the body of the catalogue. The year of publication of each book is also given to save the time of readers wishing to know of the most recent works. Another improvement in Part II is the addition of a word or two to each entry, giving a hint of the nature and scope of the book. We think that Messrs. H. K. Lewis and Co. deserve the thanks of their clients for providing a catalogue which is also a serviceable index to the current literature of medicine and the allied sciences.

In their book on the hypophysis[13] Messrs. PENAU, BLANCHARD, and SIMONNET have brought together a great amount of information culled from a study of the extensive literature dealing with the activities of that ductless gland. The volume is divided into two parts, which treat of the anterior and posterior lobes respectively. In each case it is the chemical and physiological actions of the various preparations of these lobes that are studied, and the deductions to be drawn from the evidence presented are offered both skilfully and fairly to the reader. The text is clearly arranged, and is written with a notable brevity. The book should be in the hands of all chemists, physiological workers, and medical men who are interested in the study of the hypophysis.

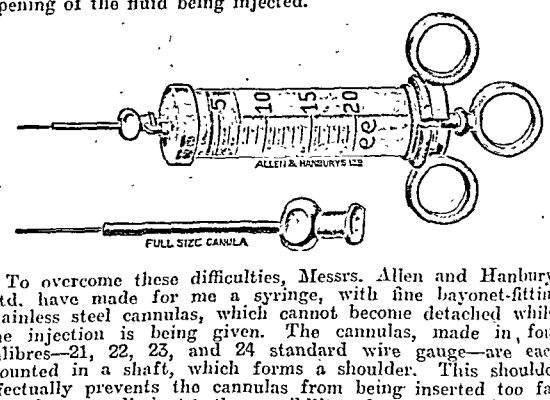
PREPARATIONS AND APPLIANCES.

A VASOTOMY SYRINGE.

MR. J. F. PEART, F.R.C.S.I. (London, W.), writes:

In making an injection into the vas when doing a vasotomy two matters of primary importance in connexion with the cannula used are: first, that its point be so constructed as to avoid damaging the inner lining membrane of the tube; and, secondly, that the calibre should so fit the lumen of the vas as to prevent, if possible, any leakage out of the vasotomy opening of the fluid being injected.



To overcome these difficulties, Messrs. Allen and Hanburys Ltd. have made for me a syringe, with fine bayonet-fitting stainless steel cannulas, which cannot become detached whilst the injection is being given. The cannulas, made in four calibres—21, 22, 23, and 24 standard wire gauge—are each mounted in a shaft, which forms a shoulder. This shoulder effectually prevents the cannulas from being inserted too far into the vas, eliminates the possibility of puncturing it lower down, and occludes the remainder of the vasotomy opening.

X-RAY INTENSIFYING SCREENS.

We have received a pamphlet from Philips Lamps Limited (145 Charing Cross Road, W.C.) describing their intensifying and fluorescent screens for supplementing the photographic action of x rays. The point is made that while a high accelerating factor is claimed for most screens on the market, the value is usually calculated by exposures made with "hard" radiation, with which the best radiographic definition may not be obtained; but that with the screens manufactured by this firm the exposures can be reduced when "soft" radiation—that is, of comparatively low penetration—is used, as in chest or kidney work.

MOULDING MATERIAL FOR CASTS.

Messrs. Apotela, Ltd. (65, Moorgate Street, E.C.2), have put on the market a hydrocolloidal moulding material called "negocoll," which, applied by brush or by hand, may be used for preparing casts of any kind of object, or of the dead or living body. The manufacturers claim that the substance is clean and simple in use, aseptic, and practically indestructible; and that objects to be copied may be faithfully and accurately reproduced without any special preparation. Two other of the firm's products—"hominit" and "celerit"—are used to make the positive from the negocoll cast.

British Medical Journal.

SATURDAY, AUGUST 24TH, 1929.

THE CAMPAIGN AGAINST RHEUMATISM.

THE gravity of the problem of rheumatism was first brought home to the public and the medical profession by a report of the British Ministry of Health, published in 1923. This report disclosed the great prevalence of rheumatic diseases among industrial workers, and the almost immeasurable suffering, disablement, and economic loss which they entail. Since that date similar conditions of widespread rheumatic invalidity have been reported in various parts of northern Europe, although it seems probable that in England some types of arthritis are more severe than in other countries. Some attempts have already been made to grapple with the problem, and in one of these attempts England and Holland have led the way. Further inquiries were instituted in 1925 by the International Society of Medical Hydrology, and a small international committee on rheumatism was formed, with its headquarters in Amsterdam. The time seemed ripe for a serious concerted effort. National committees were presently established in England, Holland, Germany, Austria, and other countries. All these committees, including the original International Committee, have now given place to independent organizations, representing not only the medical profession as a whole, but public health authorities and industrial and other public bodies in the various countries which are concerned with the health, welfare, and industrial capacity of the great mass of workers.

The movement progresses with somewhat unequal steps in the different countries. The central group, now known as the International League against Rheumatism (*Ligue Internationale contre le Rhumatisme*), of which the chairman is an Englishman and the honorary secretary is a Dutchman, is engaged in making known the widely scattered work and arranging periodical conferences between competent authorities and serious workers in all countries. The next discussion held by the League will take place at Budapest in October. Some of the national associations or societies for combating rheumatism have become the recognized machinery for dealing with a serious national question. A strong representative committee is at work in America, and in Germany and Holland the Governments have made financial grants. But in dealing with a problem having so many aspects—medical, social, and economic—it is necessary to combine the experience of many nations. International co-operation and co-ordination must complete the work of the national groups. It will be recalled that in England the Ministry of Health has foreshadowed three types of institutions for the investigation and treatment of rheumatic diseases: the arthritis unit for in-patients, which should be devoted mainly to research; the centre for physical treatment in the town, mainly for early cases and after-care and clinical investigation, carried on in co-operation with the hospitals and spas; and, lastly, a development of the spa hospital. This programme has been further elaborated in the report on arthritis by Dr. Alison Glover, published in May of last year.[1] For a programme of such magnitude it seems clear that only a well-arranged system of team work can meet the case. Many varieties of disease are in question, affecting vast numbers of people. On the one hand are problems of causation and pathology; on the other hand the practical problem of devising and directing on a large scale a systematic preventive and curative treatment. With these must be combined many necessary studies—of methods and of the effects of weather and climate, of housing and occupation, upon the persons under treatment.

It would be ungenerous not to acknowledge that much good work has already been done in this country by isolated workers, especially at the spas. We are reminded in a paper by Dr. Fortescue Fox, of which we publish a summary in another column (p. 358), that some of the English mineral water hospitals are already arthritis units in the making. They are, unfortunately, occupied for the most part with the later stages of disease. But in spite of this drawback the therapeutic results of the spa hospitals will stand comparison with those obtained under any other form of treatment. They are, moreover, thoroughly imbued with the spirit of research. The new organization, known as the National Campaign against Rheumatic Diseases, is designed to give expression and direction to this movement in England. In its "Statement of Policy"[2] the council founded itself upon the serious invalidity and economic loss occasioned by rheumatism. Research and treatment, it says, are inadequate, and the remedial measures which are known to be beneficial are available only for a small minority of sufferers. The objects of the campaign are comprehensive. They embrace: education of medical and public opinion, of the patients and their families, and of employers of labour; research, under a variety of headings; extended facilities for treatment in hospitals, clinics, and spas; standard records and classifications; and, lastly, the collection and distribution of data. If even a part of this wide field is to be covered, clear thinking will be needed, a precise division of labour, the enlistment of all serious workers who are at present engaged throughout the country in the investigation and treatment of rheumatism, a co-ordination of purpose and method, and, above all, a pervading motive force. An organization may be an empty shell, or it may become the framework of a living spirit.

To encourage and support individual work, to organize the most necessary and fruitful investigations, to make the best knowledge and skill everywhere available in treatment, are purposes which deserve and require most generous material and moral support from the Government and from private individuals. Many questions will naturally come before the council of the campaign in considering how these objects may be compassed. How can the necessary research, both clinical and in the laboratory, be best organized and allocated? Time and effort must not be wasted in blind alleys, in vain repetitions, in ignorance of previous findings. Is it proposed to set up a co-ordinating nerve centre or bureau of research? The statement of policy recommends several lines of investigation into the causes of rheumatism. Of these, some, such as the bacteriological, biochemical, radiological, and comparative pathological, are modes of research that are usually carried on in hospitals with beds and laboratories. Another series of perhaps equally important lines of investigation are enumerated: the clinical examination of cases; clinical research into the various types of disease; study of the occupational, climatic, and geographical incidence of rheumatism, and of the action and comparative

[1] See *British Medical Journal*, May 26th, 1923, p. 934.

[2] See *British Medical Journal*, July 6th, 1929, p. 36.

efficacy of various methods of preventive and curative treatment. Here, again, a little clear thinking may prevent a useless overlapping of function between different types of institutions. According to the statement of policy, the new clinics or centres for physical treatment will carry on their work in liaison with research laboratories. It is clear that the elucidation of the problem of rheumatism demands many forms of inquiry, some perhaps unfamiliar, and that, with wise allocation, the arthritis units and spa hospitals, the large general hospitals with their laboratories, and the clinics with their mass of early cases, will all have ample opportunity for much-needed and differing lines of investigation.

But, after all, the insured population are asking for treatment, and the many who suffer from rheumatism are entitled to the same measures of relief or cure which more fortunate persons enjoy or which have been found advantageous in the medical practice of other countries. All speed to research! but the machinery of treatment cannot stand still until research has been completed. Apart from the long-established and beneficent work of the spas, the first real step to cope with this problem has been taken by the British Red Cross Society. At its clinic in Regent's Park, London, which will be opened in a few weeks, a great many industrial workers, rheumatic sufferers in the towns, will be enabled to receive physical treatment in the early stages of disease near their homes and after working hours. The founders of this clinic have adopted for their principle *Solvitur ambulando*. For example, they hold that it is an integral part of the work of this pioneer demonstration clinic to scrutinize the action of the physical remedies that are employed, whether alone or in combination, with a view to determining their optimum use in the various stages of rheumatic disease. In the paper already referred to, Dr. Fortescue Fox advances his belief that what he describes as the bath complex (heat and moisture and movement) will be found to be the "master treatment" of rheumatism. Whatever views may be held by others as to the relative value of the various forms of physical treatment, many medical men will agree with him that the traditional faith of mankind is worthy of some respect, and that treatment by appropriate baths has often proved of the highest value in rheumatic cases. We are glad to note that the principal feature of the new clinic is to be a comprehensive installation [illegible] upon modern lines. At present for this mode of treatment are lacking in London. Under wise direction it should prove a therapeutic asset of no small value.

In the appeal of the British Red Cross Society for funds to establish the clinic, and in the statements made in our columns and in the public press, the intention was made clear that this first institution in the metropolis should serve as a model of scientific investigation and treatment. Want of experience and skill in its administration has been the bane of physical treatment, especially in rheumatic cases. For this reason the originators of the scheme proposed that all treatment should be given by a medical director and a staff having expert knowledge of physical methods of treatment. Similarly, instruments of precision and standard records should replace less exact procedures of examination. Among other proper subsidiary purposes, the clinic should serve as a centre for diagnosis, for teaching, and for training. To use the words of the original London Clinic Committee, "it is anticipated that young practitioners and attendants will be trained for undertaking similar work elsewhere." It is, moreover, stated that the clinic is not designed for the insured classes alone, but for the mass of men and women suffering from rheumatic affections who are able and willing to pay a reasonable fee for treatment. The position which it should occupy, with reference to existing institutions, is described in the statement that it will be conducted in a spirit of co-operation with the voluntary hospitals and the spas. Many cases must be referred to the hospitals for special treatment, and, on the other hand, it is proposed that hospitals which do not possess facilities for hydrotherapy should have the opportunity of availing themselves of the service of the clinic.[1]

The establishment of this institution, and indeed the widespread interest in the problem of rheumatism, owe much to the insight and public spirit of some of the foremost representatives of industry in England. They, after all, are best acquainted with the needs of the people that it is primarily designed to serve. It is the expression of a medico-social movement, which has sprung up from the co-operation of medicine and industry, and will be carried to success with the support and good will of all the interests involved.

UNDIAGNOSED TUBERCULOSIS.

During the last twenty years attention has been focused on the importance of the "carrier" as a source of public danger. While acute diseases—as, for instance, diphtheria, enteric, and encephalitis—raise more interest and alarm among the general public, and place a more insistent problem before the profession, than do the chronic diseases, such as tuberculosis, syphilis, or rheumatism, the economic wastage from these latter is by far the more important. The exact position of infectivity in relation to adult tuberculosis is still a matter of opinion and controversy, but, on whichever side he stands, no one can deny the importance of either the massive dose to the adult or the liability to infection of the exposed child. For this reason the "carrier" or undiagnosed consumptive should be regarded as a factor of no mean importance in the problem of the incidence of tuberculosis in the individual or in the community. The tubercle bacillus is seldom met with save in the bodies and in the excreta of the tuberculous, but this is largely because it is not often looked for. Public health regulations are more concerned with the adulteration of our food and drink supply by organic or inorganic poisons than by bacterial ones. The exact vehicle for the spread of the tubercle bacillus may be unknown, but Calmette's suggestion that the human body, wherever infected, may excrete the bacilli via the bile and the large intestine is pregnant with possibility, and (menacing as it does, like enteric, our uncooked food and drink supply) is worth investigation. Coupling this with the further suggestion that the tubercle bacillus may assume a non-acid-fast and hitherto unrecognized form, both within and without the body, grave possibilities of danger from the undiagnosed consumptive may be imagined.

Dr. Fishberg, in his address to the British Medical Association at Manchester (printed at page 331), has crystallized our past and current conceptions of chronic pulmonary tuberculosis into apical and subapical types, and his accurate clinical delineation of the apical type as a mild, chronic, and often unrecognized condition affords us at once a plentiful "carrier" supply,

[1] See Memorandum, *British Medical Journal*, November 12th, 1927, p. 893.

whether we look on sputum as the excretory vehicle or whether we incline to believe in the stealthier method envisaged by Calmette. Opie and McPhedran have shown that apical infiltration is not an uncommon finding in symptomless children exposed to gross tuberculosis in the working-class home; it seems to be an alternative primary childhood lesion differing intrinsically from Ghon's primary focus with its corresponding involvement of the tracheo-bronchial glands. Presumably, therefore, Fishberg's apical types may have their origin in early life, and thus may have a longer "carrier" career than is commonly supposed. It can well be argued that such "carriers" are a far greater danger to the public health than the frankly recognized consumptive. The majority of those who have been diagnosed and notified spend some period of their lives in tuberculosis institutions where the importance of personal hygiene in its relation to the spread of infection is taught. That they all benefit by or follow out their teaching is not so certain, but even if they do not, close personal contact with them is avoided by those who know them. They are marked; and the stigma often brings to them a burden additional to that of their chronic disease. Although recovered in health, and sorely needing their steady wage to maintain that health, they find their work no longer open to them. The employer, suddenly solicitous, cannot allow such a leper to mix with his workpeople. Many of our Government departments even require a certificate of tubercle-free sputum before reinstatement. Such regulations are scarcely logical; they take no account of the possibility that the infection may have occurred during employment, or that the greater danger may be that of employing apparently healthy unsuspected carriers. The conception of infectivity without ill health is not yet commonly embraced where tuberculosis is concerned. It is not to be suggested that the unsuspecting "carrier" should be ferreted out and branded also—that would be adding hardship to hardship. The victimization is illogical. It would be interesting to know how many of those who will not re-employ a consumptive worker make the slightest effort to inquire into the tubercle-infective potentialities of those who minister to, or are in close personal contact with, themselves or their children. They do not do it; it is not a practical necessity; nor is it a practical necessity to victimize the notified consumptive. Not to re-employ the consumptive may be quite logical and just upon other grounds, but not on the grounds of his infectivity to fellow workers, save where the working conditions are so insanitary that they are a danger in themselves.

It is still an open question whether the prevention of tuberculosis should be attempted by the control of infection or by the immunization and prophylactic handling of the infected. The real laws of the infectivity of tuberculosis have yet to be worked out before this problem can have even a hypothetical solution. But when it is realized that for the urban working-class child population the incidence of infection is between 90 and 100 per cent. by the age of 15, and that American post-mortem figures show an incidence of pulmonary lesions of nearly 100 per cent. by the age of 21, the universality of infection must be admitted and realized. (It would be a better thing for our national health if this was more widely realized by the general public.) If infection is universal—and yet only a fraction of the population actually suffer or die from the disease—it must follow that the ordinary infection is relatively unimportant, and that either massive infection or some other factor must be the determining agent. But people apparently do enter adult working life infected and probably harbouring living bacilli; as such they are potential consumptives. It would seem, then, that a closer study of tuberculosis in the child, combined with a "following up" in adult life, would put us in a position to classify the different degrees of intensity of infection and of extent of lesion that are found at adolescence and puberty, and to determine what risk there was for any given degree of infection, in any given circumstance, to develop into frank consumption. From this knowledge it would be but a step to the organization of a real preventive treatment, to which probably no disease is more amenable than tuberculosis. How apposite are the words of Dr. Savage in his book[1]: "Too often we seem content to succour the damaged traveller along life's road by tending his hurts with food and sun and maintaining him at an inn . . . until he is sufficiently recovered to hobble away, but never taking adequate measures to police the road from Jerusalem to Jericho. The Samaritan has his welcome place in the scheme, but the preventive force is an urgent need."

We publish elsewhere (at page 335) a paper on hilus tuberculosis by Dr. Gair Johnston, dealing with the examination of no fewer than 20,000 children; and Lissant Cox and "others"[2] publish figures relating to the same subject with an experience of 1,500 children. It is from works such as these—and they are being contributed from every country—that we shall get the basic facts, and from them we may build a scheme, not, perhaps, to prevent infection, but to harness it and to make it harmless.

RAY LANKESTER.

By the death of Sir E. Ray Lankester the world has lost one of its great men. He was the Samuel Johnson of modern science. He was big in body and in mind, brimful of humanity, and knew how to enjoy the best life had to give. He assumed leadership in his youth and, by strength of courage, a forceful personality, and soundness of judgement, maintained a dominating ascendancy almost to the end, which came, on August 15th, in his eighty-third year. He was intolerant of restraint, and the unsleeping enemy of sham and pretence. The effects of his life's work were not confined within the bounds of science, but overflowed and permeated the great tide of public thought beyond.

The career of Ray Lankester compels us to realize how greatly the face of medicine has changed and is changing. He taught medical students, and yet, although the son of a medical man, he himself was not trained for medicine. When he became a graduate of Oxford in 1870, at the age of 23, biology was growing into an independent kingdom. Up till then men who wished to devote themselves to comparative anatomy, zoology, botany, or other accessory subjects such as physiology, found it necessary to enter them by a medical portal and seek for a post in connexion with a medical school. By 1870 biological knowledge had so grown, and the training for all research into the processes of life had become so technical, that the leaders of the time—particularly Huxley—advised promising young men to take courage in both hands, cut themselves free from the skirts of medicine, and devote themselves whole-heartedly to their chosen branch—be it zoology or physiology. Hence we find Ray Lankester, on leaving Oxford, going to the

[1] *The Prevention of Human Tuberculosis of Bovine Origin.* By W. G. Savage. Macmillan and Co. 1929.
[2] *Tubercle*, vol. x, No. xi.

Zoological Station at Naples in place of entering a medical school in London. At the age of 27, when under the old dispensation he might have expected to have his name on a brass plate in Harley Street and hold a lectureship at a medical school, he found himself professor of zoology at University College, London—a stepping stone to the Linacre chair of comparative anatomy at Oxford, whither he went in 1890 at the age of 43. Two years later he was recalled to London to succeed Sir William Flower as director of the Natural History Museum, South Kensington. His predecessors there, Owen and Flower, had both entered zoology through the customary medical portal. At South Kensington he remained until 1907, when, having reached the age of 60 and the very height of his ability and fame, he was relieved of office in order that official wheels might run along undisturbed in their well-worn ruts. No power on earth, save death, could "retire" Ray Lankester. For twenty years he broke the bread of science to English-speaking people, and in this role he had no equal. He had ranged the whole realm of life; his methods were exact and his observation sure; he knew at first hand the smallest forms of life as well as the largest; he was never the slave of his facts; his mind moved easily over great fields of living things, perceiving the interrelationship of one to the other, and the whole to the great problems of human civilization.

From his youth upwards Ray Lankester was under the spell of Huxley; he was by far the greatest of Huxley's disciples. No one perceived the extent and power of his youthful abilities better than did Huxley; and no one realized more accurately the rocks on which such great abilities might become wrecked. When, in his earlier years, Ray Lankester sought to serve the British Association as a secretary, Huxley's remark to him was: "Lankester, a secretary to the British Association has to suffer fools gladly; I have observed that you gladly make fools suffer." Ray Lankester acted on this principle all through life. He was appointed to the chair of natural history in Edinburgh; he accepted it, occupied it for a fortnight, and then flung the gift at the heads of the givers. He quarrelled at Oxford; he was obstreperous at South Kensington; he had an unpleasant passage with the police in Piccadilly. He was marked out by his ability and accomplishments to occupy the presidential chair at the Royal Society; but his colleagues feared what might happen to the routine machinery of the society were he to become its president. He had the impatience of an autocrat, but it was an honest impatience. Having satisfied himself that a certain change would conduce to the advancement of knowledge and of liberty, he could not believe that the opposition of his opponents was due to anything else but wilful obstinacy, and that only sledge-hammer methods could remove the obstruction. No one could wield the sledge-hammer with more effect than Ray Lankester; and yet in the midst of apparent victory he suffered defeat.

Ray Lankester's greatest character was his fearless courage. No matter how unpalatable a truth might be, once he had persuaded himself that it was well founded no self-interest came between him and its open proclamation. He refused faith as a guide, and strove in all things to follow the dictates of reason. He inquired into the manifestations of spiritualism, and found that the "facts" on which its verdicts were based were such as could not pass muster in any scientific inquiry. Perhaps no finer example of his courage could be cited than his championship of the discoveries of Mr. J. Reid Moir of Ipswich. In 1910 Mr. Reid Moir was seeking to convince men of science that the rosto-carinate flints which he had found under the "red-crag" of Suffolk had been fashioned by human hands. Geologist [illegible] archaeologists looked on with [illegible]ticism until Ray Lankester [illegible] the evidence at first hand, convinced himself that Mr. Reid Moir was right, and immediately set about to vindicate his claims, and persisted until he won a hearing for the youthful discoverer.

When Ray Lankester began his career zoology was believed to have suffered in the servitude of medicine. John Hunter had made zoology an appanage of medicine by seeking in it clues to function. Then came in succession Cuvier, Owen, and Huxley, who made zoology a study of form and initiated the period of morphology—a functionless zoology. At the height of this period Ray Lankester began his career, and became the most eminent morphologist of his time. If morphology provided no profitable food for medical men, that was their look-out rather than his. And yet he was proud that zoology could serve in the progress of medicine; he was ever ready to cite the important contributions his friend Metchnikoff had made to practical medicine. He lived to see the younger and more daring recruits to zoology abandon the field of morphology and devote themselves to the study of living processes—processes of development, nutrition, growth, and reproduction. It was not given to Ray Lankester to open the portal that led to a great field of new knowledge, but there is scarcely a compartment of zoological knowledge that has not been extended and improved by his visit to it. He was the last of the great morphologists, and, although the methods and aims of zoology may alter, yet his work can never pass out of date, because it is founded on the rock of truth.

POSSIBLE DANGERS OF COD-LIVER OIL.

THE fact that the administration of cod-liver oil is by no means an invariably safe proceeding is becoming increasingly clear, and on two previous occasions (1928, vol. i, p. 639, and 1929, vol. i, p. 165) we have commented on the nature of the risk. The investigation of this highly important subject has for the most part been reported in *Acta Paediatrica*, and a recent number of this periodical[1] is almost entirely devoted to a study of the problem from several points of view. P. Henriksen, after an extensive survey of the results on the body cells of vitamin A given either in excess or in deficient quantity, comes to the conclusion that general cell degeneration throughout the body may be produced by large doses. In his experiments on young rats doses of over 1.4 grams of cod-liver oil per kilogram of body weight caused such degeneration. He strongly criticizes certain previous workers, however, and especially Agduhr, for suggesting that cod-liver oil may be dangerously poisonous to the heart, and may even lay the foundation of future heart disease. Agduhr replies to these criticisms in the same number of the periodical, pointing out that he was himself considerably puzzled by the lesions found in the hearts of certain experimental animals which were given toxic doses of cod-liver oil; in order to take the matter a step further he has studied, in conjunction with Dr. N. Stenström, the appearance of the electrocardiogram in heart lesions produced by cod-liver oil treatment. From the outset of these experiments it was necessary to determine the appearance of the normal electrocardiogram of white mice and also what variations in the rhythm of the heart might occur quite apart from cod-liver oil intoxication. It was ascertained that after

[1] *Acta Paediatrica*, June 12th, 1929, vol. viii.

the animal has passed the first period of growth, lasting for about the first month of life, the electrocardiogram remains practically constant during the period of life covered by the experiments. At first, as a result of studying some seventy mice, it was proved that even highly pronounced morphological heart injuries could be present without the electrocardiogram showing any obvious changes from what at this time could be regarded as the normal. When animals were followed more exactly over a longer period of time certain definite changes were observed, especially in the ventricular part of the electrocardiogram, which altered its features so consistently that the experimenters were able to recognize it as "a typical cod-liver oil electrocardiogram." In addition, the auriculo-ventricular conduction time was prolonged in animals treated with cod-liver oil, in many instances to a pathological degree. The exact mechanism of these disturbances of the cardiac contraction appears to be uncertain, but there is a definite correlation with the morphological changes observed in the cardiac muscle. In less than one year mice showed alterations in the electrocardiogram with doses of even such small amounts as 1/7 c.cm. of cod-liver oil per kilogram of body weight daily. This would correspond bulk for bulk with approximately 25 minims of cod-liver oil daily for a 12-months-old infant, but the whole question of differences of susceptibility has to be taken into account. C. W. Herlitz, I. Jundell, and F. Wahlgren contribute yet another paper on this subject, with reference to the harm done—more especially to the heart—by the antirachitic substance. They conducted a series of extensive and elaborate experiments on animals, and showed that doses of this substance, quite comparable with those employed in clinical medicine for children, could produce considerable degenerative changes in the cardiac muscle. They feel very strongly that the public should be warned about the danger attending the indiscriminate use of cod-liver oil and also of various forms of irradiated milk. Taking the three papers here considered as a whole there still seems to be some difference of opinion as to the effects of cod-liver oil in ordinary therapeutic doses, but the subject is of sufficient importance, and the present evidence is suggestive enough, to warrant a more intensive study, so that a definite answer may be given to the question—can cod-liver oil do harm?

SAFETY AND HEALTH IN COTTON SPINNING MILLS.

FOLLOWING a recommendation of the 1911 Departmental Committee on Accidents, representatives of employers and employees in the cotton spinning industry met representatives of the Factory Department in conference, and, by July, 1912, had agreed upon a series of safety measures against accidents. These were duly embodied in regulations which admittedly have been very successful in diminishing both the incidence and severity of such accidents. The passing of time has, however, brought to light the fact that not all the precautionary measures are proof against the carelessness and perverseness of the human element, or are sufficiently rigid in themselves. As a result the conferences were reinstituted at the end of 1926, and their chairman, Mr. E. F. May, a superintending inspector of factories, has now issued a report.[1] The agreements do not, in all cases, carry out the excellent preliminary suggestions put forward by the chairman, but they convey a general impression of a useful tightening up of the loose elements so far as safety is concerned. There are, however, two outstanding amendments which should prove of great value; one compelling a definite signal from the spinner to the cleaner before the latter enters the danger zone between the movable carriage and the fixed part of the mule, and forbidding restarting before his reappearance, the other being the formation of a joint standing committee to consider from time to time the desirability of amending any of the regulations. Mule spinners, who work with their feet bare, are very subject to slight splinter wounds which rapidly become septic, but, as the operatives object to slippers and the employers cannot afford maple floors or composition coverings, the only remedy suggested is the providing of readily accessible iodine, forceps, and sterilized dressings, and of "a person instructed in their proper use." This is a confession that no preventive measures against the primary injury can be recommended, which makes us inclined to think that the inexpensive slipper might have had more encouragement. Canvas shoes with hempen soles do not slip, and have made headway when provided and pushed by a welfare department. Apart from the general weakness of the recommendation we note that nothing is said as to how the person in charge is to get the essential instruction for dealing with splinters. It would be quite easy to get the necessary help from the certifying surgeon, who is frequently reporting on first-aid equipment in cases of sepsis and poisonings, and is regularly visiting the mills, but apparently there was no thought of this safeguard. The really comfortable way in which temperature is dealt with by just readopting the 1912 standard calls for some comment. Card rooms and ring spinning rooms, grouped together for some reason that is not obvious, are allowed a maximum of 80° F. and a minimum of 60°, mule rooms are allowed a maximum of 95° and a minimum of 70°; artificial heating is to be cut off when a maximum is reached, but a maximum may be exceeded during hot weather. This is, obviously a rule-of-thumb scale and, so far as spinning rooms are concerned, makes no pretence of dealing with the real problem. One illustration will readily justify this criticism. In cotton spinning as well as in weaving, a certain amount of relative humidity is a necessity, and to maintain the correct percentage with a rising dry bulb temperature there must necessarily be a corresponding rise in the wet bulb temperature. In fine-spinning rooms, where temperature and humidity can be accurately regulated, the best results are gained at a relative humidity round about 45; but to maintain even this reasonable percentage a dry bulb temperature of 95° would mean the wet bulb temperature rising to 80°. Now a recent report of a departmental committee on artificial humidity in cotton weaving told us that "a wet bulb temperature of 75° is a critical point in regard to the injurious effect of the atmosphere on the human body, but that the discomfort and decline in productive efficiency make themselves felt before that temperture is reached," and as a direct consequence of that dictum the 1929 weaving regulations insist that artificial humidification must cease when the wet bulb temperature exceeds 72.5°. There are other points needing consideration, but the one brought out should be sufficient to convince the trade that it would be a wise step to set the new committee functioning by instructing it to make a thorough investigation into the significance of high wet bulb temperatures in spinning rooms. The members will find plenty of useful information in the temperature and humidity section of Dearden's Milroy Lectures.[2]

ANNUAL REPORT OF THE MINISTRY OF HEALTH.

ONLY a man of the most catholic taste or one loving detail for its own sake could be expected on first acquaintance to traverse the pages of the annual reports of the Ministry of Health without pause and without bewilderment. The ramifications of the system—or systems—of administration under the control of the Ministry are so extensive and so

[1] Home Office Report on Conferences between Employers, Operatives, and Inspectors Concerning Fencing of Machinery, Prevention of Accidents, First Aid, and Temperature in Cotton Spinning Mills. By Eliot F. May. London: H.M. Stationery Office, or through any bookseller. 1929. 3d net.

[2] W. F. Dearden: Health Hazards in the Cotton Industry. *British Medical Journal*, March 12th, 1927.

diverse that it is exceedingly difficult to form any clear picture of its activities or to choose any outstanding feature in the tale of its labours. In the year ended March 31st, 1929, covered in the most recent report,[1] the most notable event in the history of the Ministry was the passage of the Local Government Act, 1929, which, as the report reminds us, is a logical development of the policy instituted in 1919 in the Act which established the Ministry itself, and which marked the beginning of an effort to co-ordinate the health services of the country into one comprehensive and economical system. The report under review is divided on the conventional plan into five sections, devoted respectively to public health, local government and local finance, administration of the Poor Law and old age pensions, national health insurance and contributory pensions, and the activities of the Welsh Board of Health. In the section given to public health it is stated that further progress has been made in the development of the tuberculosis service by local authorities, notably in the number of beds provided by such bodies in their own institutions for the treatment of the disease. Progress has also been made in the provision of facilities for orthopaedic treatment and for actinotherapy. The attention of local authorities has been directed to the experimental work of the National Association for the Prevention of Tuberculosis at Burrow Hill, Surrey, where youths between 14 and 19 are being furnished with technical instruction while undergoing treatment for tuberculosis. In discussing the notification of tuberculosis, emphasis is laid on the need for caution in accepting statistics relating to the incidence of tuberculosis owing to the fact that the accuracy of the notification registers is open to question. It appears that in certain areas the registers, through insufficient care in revision, are inflated with cases which for various reasons should have been removed. Deaths from tuberculosis show a further decline, the mortality rates of 755 and 173 per million population from pulmonary and non-pulmonary tuberculosis respectively for 1928 being the lowest ever recorded in this country. Details are given of the steps taken to combat maternal mortality, and, although no comparative figures are given, the report states that the numbers of local authorities making special arrangements for the institutional treatment of puerperal fever and puerperal pyrexia, for the services of specialists for consultation, and for skilled nursing show "a material advance." The number of infant welfare centres has also increased, and while there is little actual change noted in the extent of the provision for complicated cases of confinement, several notable additions to this type of hospital accommodation are being made. A section of some interest to insurance medical practitioners explains the policy and procedure of the Ministry in relation to the vexed question of excessive prescribing; in the course of the year money was recovered from practitioners on this account in only 21 cases, the aggregate amount so recovered being about £370. In view of the fact that there are about 14,300 doctors in England in insurance practice, and that over £2,000,000 was expended in the year on drugs and appliances, there seems ground for suggesting that much more has been heard of "excessive prescribing" than the facts of the position justify. Many other points of similar character to those mentioned emerge on study of the report, but it cannot be regarded as a satisfying type of document. The various sections are concerned for the most part with administrative and financial questions, the medical cream of the year's work being presented in the report issued separately by the Chief Medical Officer, while the main vital statistical returns are issued by the Registrar-General. Consequently the report of the Ministry itself comprises chiefly a collection of information on points of detail—invaluable for reference but uninspiring in the mass. No effort is made to present even a brief rounded sketch or summary of the Ministry's main achievements, and in view of the importance of the subject, and of the need for the education of all sections of the public and the lay press regarding the complex system of health administration, this must be regarded as a matter for some regret.

FLICKER AND VISION.

THE report of a new piece of research work by Messrs. Lythgoe and Tansley has been issued by the Medical Research Council.[1] It deals with the adaptation of the eye, and its relation to the critical frequency of flicker. A knowledge of the behaviour of the eye in different states of its adaptation is obviously of great importance for all occupations involving vision at low illuminations, and within recent years it has become recognized that adaptation may also play a prominent part in the performance of visual tasks at higher illuminations, since it is then controlled chiefly by the characters of the surrounding field of vision. In this new work the variations in the critical frequency of flicker under different states of adaptation of the eye have been studied. It has been recognized from very early times that the sensation produced by a visual stimulus persists after the stimulus itself has come to an end, and this persistence of vision was used by Aristotle in his explanation of dreams. D'Arcy measured the rate at which a burning stick had to be whirled round before it would give the impression of a continuous circle of light. The modern method of measurement is a refinement of this test. A disc with sectors cut out is rotated in front of a source of light until flicker gives way to a sense of continuous light. The values of the critical frequency of flicker depend on the intensity of the light used; the brighter the light the faster must be the revolutions, and this gives a measure of the different values of the light. It was found that at low illuminations the critical frequency rises slowly with increase of illumination. At higher illuminations the critical frequency measured by the fovea rises much more rapidly, so that it is higher than for the periphery, and the reverse for low illuminations. The influence of surrounds was also investigated. One of the authors had noted that when in a train among the snowfields in Switzerland the flicker of the electric lamps was very noticeable on a bright day with the sunlit snowfields in view, whereas during the passage through a lengthy tunnel the flicker was inappreciable. In these tests it was possible to differentiate the reactions of the rods and cones of the retina. In the course of their experiments they were able to demonstrate that one of their subjects was night-blind. On the Archangel front during the war night-blindness among the troops was a common occurrence. The condition yielded to treatment with cod-liver oil, which contains vitamin A. On inquiry it was ascertained that their laboratory worker, who gave reactions of night-blindness, ate practically no butter or fresh vegetables, and drank no milk or cream.

THE PRIMARY F.R.C.S. EXAMINATION IN CANADA.

A PRIMARY examination in anatomy and physiology for the Fellowship of the Royal College of Surgeons of England was held at Toronto on August 6th and the following days, this being the first occasion on which this examination has been held out of England. It was conducted by Professors William Wright, W. E. Le Gros Clark, C. Lovatt Evans, and John Mellanby, who were sent out from England for

the express purpose, with Professors J. P. McMurrich and C. H. Best of Toronto University as assessors. Sir Holburt Waring also attended as visitor on behalf of the English College. Twenty-three candidates presented themselves for examination, and nine were successful. The Canadian Medical Association was responsible for the arrangements, and much of the success of this new departure was due to Dr. Alexander Primrose, dean of the Medical Faculty of the University of Toronto, and Dr. T. C. Routley, general secretary of the Canadian Medical Association, who took an active part in bringing about this attempt to offer to Canadian medical practitioners greater facilities for obtaining the F.R.C.S.Eng. There is a strong desire in Canada for closer association between the medical profession in the Dominion and in this country, and much interest has been taken in Canada and the United States in the undertaking. The examiners were received by the Governor-General at Quebec and by the Prime Minister at Ottawa, who expressed sympathetic interest in their mission. The Final Examinations for the Fellowship will be conducted only in England, but the opportunity of passing the primary examination in Canada should make two visits to this country unnecessary, and so, it is hoped, bring the F.R.C.S.Eng. within the reach of a larger number of Canadians than has hitherto been the case.

MEMORIAL TO PROFESSOR WIDAL.

WE have received from Sir Almroth Wright a copy of a letter addressed to him by Drs. Fernand Bezançon, André Lemierre, Pierre Abrami, Marcel Brulé, Edouard Joltrain, and Louis Pasteur Vallery-Radot, inviting his co-operation in a memorial to Professor Fernand Widal, who died on January 14th last. The letter announced the setting up of a committee for the purpose of placing medallion portraits of Professor Widal in the Paris Faculty of Medicine and the Hôpital Cochin, and of publishing a collected edition of his works. A number of his colleagues in other countries having stated their desire to associate themselves with this project, the signatories expressed the hope that Sir Almroth Wright would take the initiative in making the proposed memorial known to those in this country who have had personal association with Professor Widal and cherish his memory. Contributions to the fund may be sent to the *Lancet* Office, 423, Strand, W.C.2, addressed "Widal Memorial, c/o the Editor, the *Lancet*."

THE EDUCATIONAL NUMBER, 1929.

OUR next issue, dated August 31st, will be the annual Educational Number of the *British Medical Journal*. Its contents, as in previous years, will include a full account of the requirements of the General Medical Council and of the universities and other licensing bodies in Great Britain and Ireland, as well as information about the opportunities offered by the various medical schools and other teaching institutions, and the fees charged by each. The details given have been revised and brought up to date by the authorities concerned. These sections, the object of which is to furnish a handy guide to intending students of medicine, are supplemented by articles intended for newly qualified practitioners on such matters as post-graduation study, the public health services, tropical medicine, psychological medicine, and the various special diplomas. In the sections dealing with the public services will be found a concise account of the present terms and conditions of service in the R.N.M.S., the R.A.M.C., the I.M.S., and the R.A.F.M.S., which the Representative Body of the British Medical Association has decided are satisfactory and such as can be commended to the notice of the younger members of our profession. The opening articles for this year's Educational Number will be an address on "Medical Education and Licensure in the United States of America," by Sir Norman Walker, Direct Representative for Scotland on the General Medical Council; and the introductory paper on "The Place of Human Physiology in the Training of Medical Students," read by Professor Francis R. Fraser to the Section of Physiology and Biochemistry at the Annual Meeting of the British Medical Association in Manchester.

ULTRA-VIOLET PUBLICITY.

WE published last week a paper by Dr. A. Eidinow on "The effect of radiation on resistance of rabbits to infection with virulent staphylococci." This paper had been *strongly commended to our notice by Professor Leonard Hill*, in whose laboratory at the National Institute for Medical Research the author had conducted the investigation. No one outside this office, except Professor Hill and Dr. Eidinow, had been informed that it was provisionally accepted. On the afternoon of August 14th, while going to press, we learnt with surprise that the night edition of the *Evening Standard* of that date had an article on its front page, under the headings "Fighting Deadly Bacteria. Remarkable Claim by Two Scientists. Ultra-Violet Rays and Blood Poisoning," which stated that details would be published shortly of exhaustive experiments carried out by Professor Hill and Dr. Eidinow of the National Institute for Medical Research. On the same evening the British Broadcasting Corporation issued an announcement from 2LO to the effect that the results of certain experiments by Professor Hill and Dr. Eidinow on the use of ultra-violet rays in blood poisoning would be published shortly in the *British Medical Journal*. This announcement, it need scarcely be said, was not authorized by us, and we have impressed upon those most immediately concerned that it is their duty to trace the leakage. Professor Leonard Hill, we understand, is abroad, and is probably not aware of these occurrences.

THE Board of Control (England and Wales) has issued a report by Surgeon Rear-Admiral E. T. Meagher, R.N. (ret.), on the treatment of general paralysis by induced malaria. It embodies a study of over 1,500 cases, and the evidence collected is considered to justify the conclusion that beneficial results are obtained in this way which are specifically attributable to the treatment. The report is a long one, dealing in detail with numerous cases; we hope to discuss its findings in a later issue. It is published by H.M. Stationery Office at the price of 2s.

WE publish in the *Supplement* this week the full text of the annual report for 1928-29 of the Insurance Acts Committee.

COMMENTING on Sir Donald MacAlister's approaching retirement from the principalship of the University of Glasgow, *Nature* of August 17th says: "Sir Donald's resignation brings to an end a principalship the success of which is probably unprecedented in the annals of Scottish universities. During the past twenty-one years the University of Glasgow has made remarkable progress, due mainly to the principal's genius in administration. He soon introduced great improvements in the business of the university, and has unquestionably made it a far more efficient and competent organization. Before he took office there had been frequent friction between the University Court and Senate: but his capacity as chairman of the court, and the full confidence of the teaching staff in his judgement, insight, and statesmanship, have allowed the court without opposition steadily to increase its control of the university."

THE TREATMENT OF RHEUMATISM BY BATHS.

THE *Archives of Medical Hydrology* for the current month (August) contain a number of papers and reports bearing on the treatment of chronic rheumatic diseases. By this term the authors signify all those forms of arthritis, myositis, fibrositis, and their congeners which appear to be the peculiar liability of those who live in cold, damp climates. Among the more important papers reviewed are those presented at the recent meeting at Aachen of the German Society for Combating Rheumatism and Professor H. Strauss's work on "Rheumatism and chill."

Principles of Thermal Treatment.

The application of physical remedies to diseases which have a climatic element in their causation is an attractive conception. For many years Dr. Fortescue Fox has been an exponent of this idea, and the rheumatic diseases are here cited as a strong case in point. His suggestive paper on "The value of baths in rheumatism" is the fruit of long experience in the sphere of hydrology. Dr. Fox discusses the operation of uncompensated cold in the development of rheumatism, and expresses his conviction that stimulation of the skin by heat, moisture, and movement in baths is by far the most effectual form of physical treatment in the protean forms of this disease. He is far from decrying the influence of other causes, extrinsic and intrinsic, in the development of rheumatism. The infective factor is, for example, clearly present in a proportion of cases; but Pasteur long ago showed how easily exposure to cold might make infection operative.

The argument is an interesting one. The functional disturbances which occur in the early stages of rheumatic illness are precisely those which are observed to follow exposure in individuals sensitive to cold.

> "The circulation of the blood is withdrawn to the vital organs, and the temperature falls, first at the exposed surface and afterwards in the deep parts. . . . Failure of the normal reaction to cold lowers the temperature of the body and prevents the movement which in its turn would generate heat. . . . The various rheumatic diseases met with in cold climates may be described, functionally, as a failure of movement due to a deficiency of heat, and anatomically as lesions of the apparatus of movement. . . . The reactions of uncompensated cold are nothing more nor less than the functional disturbances which accompany the development of rheumatic disease."

From this position Dr. Fox goes on to consider some of the effects in the tissues and organs which can be produced by stimulation of the skin. The reactions produced by the "bath complex" (heat, moisture, and movement), in their nature and in their distribution, are just those which the physician seeks to obtain in order to relieve the symptoms and the associated disorders of function which distinguish the development of rheumatism. Cutaneous stimulation by heat, more especially in rheumatic cases, carries in its train a series of increments: increase of all the functions of the skin itself, of the circulation of the blood and lymph, of metabolism, of elimination (detoxication), of involution and resorption of exudations and deposits, and of the nutrition of wasted muscles. With all this increase of functions, symptoms are at the same time diminished—chill, pain, tension, swelling, stiffness, and immobility. And these effects of baths are precisely the reverse of the effects of uncompensated cold.

But much will depend on the degree and duration and spacing of the doses given. It is also important for the effectual treatment of rheumatism that repeated thermal impressions should be supported and made continuous by a thermal environment. The effect of heat must not be immediately annulled, as so often happens, either under the mistaken idea that it is well to "cool off" after the bath, or from accidental exposure to cold in the bath establishment or hospital. This want of understanding of thermal treatment has, more often than not, vitiated its use in rheumatic diseases. A thermal environment is a necessary part in the treatment of rheumatism: the artificial climate of the bath itself should be reinforced by an atmosphere of a certain character in the building in which the treatment is given. Properly heated establishments, whether they be physical clinics or hospitals, are a *sine qua non* in the treatment of rheumatism in cold countries." Dr. Fox notes the remarkable benefit obtained in cases of arthritis by mud baths given at a spa in a hot climate. The action of the hot mud becomes day by day cumulative and even permanent in its effects, when it is reinforced by a suitable thermal environment in which the possibility of chill and even of cooling is prevented. On the other hand, it is unfortunately a common experience that the same modes of treatment, and indeed baths of any kind, given in cold climates are often disappointing, and may be injurious. The Romans got over this difficulty in Britain and Gaul by warming the pavement of their *thermae*, which produced an "artificial climate" for the bathers.

Organization of Bath Clinics.

If such general considerations be accepted, the next step is to suggest the principles which ought to govern the systematic thermal treatment of rheumatism. The British Red Cross Society has now nearly completed a central demonstration clinic in London, in which the main feature will be a comprehensive equipment of medical baths. With this are included accessory forms of physical treatment by light and electrical currents. This central clinic should provide an opportunity for investigations that are much needed at the present time. The various modes of bath treatment which have been employed in different countries for many years have yielded encouraging results. It is very desirable that all these modes of treatment should be precisely studied by modern methods. The reactions which they produce in different types of rheumatism ought to be observed and recorded accurately *pari passu* with this analysis of treatment goes the investigation of large numbers of cases in the earliest stages of disease, and especially of those functional disturbances which precede organic changes in many at least of these cases.

The clinic in London for the physical treatment of rheumatism is new in its purposes and scope, and the medico-social conception which it embodies is necessarily an experimental one. Such an institution does not exist in England, nor has it any Continental prototype. Much will depend on the lines that are laid down for its constitution, and on the programme which it sets out to accomplish.

Since it is obviously impossible, on financial and social grounds, to send the mass of industrial workers suffering from rheumatism away from their homes and work for treatment at the spas, proposals are being made for setting up town clinics in various centres in England where they may obtain the treatment they require, if necessary after working hours. Dr. Fox suggests that this need can best be met by providing throughout the country a well-tested and approved system of *bath clinics* for out-patients, in specially warmed buildings, with adjuvant forms of physical treatment, under experienced and skilful administration. Many forms of baths can be used with advantage in the successive stages of rheumatic disease. "*In the earliest* stages, the period of functional disturbance, baths are *preventive*; in the protracted sub-inflammatory stages, baths are *curative*; in the later post-inflammatory stages, baths are *palliative*."

Dr. Fortescue Fox concludes his paper with a description of four distinctive methods of bath treatment, which in his judgement are of sufficient value to justify the erection of a clinic or clinics for each of them. These are: (*a*) *Manipulation pools* and baths, with preparatory radiant heat or hot air; (*b*) *mud baths*—half-baths and packs—with galvanism; (*c*) *vapour baths*, with light, friction, and switchings, especially for early and preventive use; (*d*) *salt baths*, with manipulation. The British low-pressure manipulation douche and a proper selection of local baths should be provided at all clinics for rheumatism. But in setting up bath clinics in the towns no attempt should be made to install in one place all the methods which are employed in other places. "The best results in rheumatic cases are often obtained by a few methods, wisely employed."

In outlining such a policy it must be emphasized that, in the interests of the patients themselves and upon scientific grounds, these several procedures should be worked out by competent hydrologists. For—no less than with the modern technique of treatment by electricity, light, and radium—medical baths have proved themselves a specialty, requiring long training and skill in their use.

NATIONAL HEALTH INSURANCE IN SOUTH AFRICA.

In an article in the *British Medical Journal* of April 21st last year (p. 673), published as one of the results of the official visit of the Chairman of Council to South Africa, we pointed out that the medical profession of the Union, as indeed the whole of the British Medical Association, is vitally concerned with the development of proposals relating to the establishment of a national health insurance system in that country. The Parliamentary Commission appointed by the Governor-General in February, 1926, to examine and report upon old age pensions, and on an insurance system against the risks of sickness, accident, premature death, invalidity, and maternity, issued in April, 1927, its report with regard to the former part of its reference, and has now published a second report dealing with the latter part.[1] It is a document of great importance, and should be studied in detail by all members of the medical profession in South Africa, and by all those who are concerned with the national health insurance system in Great Britain and with schemes for social insurance in general. It contains chapters on insurance against accidents (employers' liability) and on invalidity and old age pensions in continuance of proposals made in the former report, but further reference to these matters need not be made here. In the main part of the report concerned with sickness insurance there are not merely the outlines of a scheme of national insurance with recommendations referring thereto, but many interesting and valuable notes on health insurance schemes in Great Britain, Germany, and other countries.

In the article in the *Journal* to which we have referred it was made clear "that conditions in South Africa differ radically from those in Great Britain, or indeed in any other country which has adopted a scheme of national health insurance, and that therefore no existing scheme could be applied without fundamental alterations." Certain questions were raised with regard to such fundamental points, and some suggestions were made for dealing with them. It is interesting to note that with regard to most of these the proposals now put forward by the Commission are on the lines there indicated. We referred to "certain regions as in the unsettled or pioneer stage and therefore outside practicable medical provision." The Commission is of opinion that a scheme of health insurance in such areas is impracticable, and recommends "the provision of a partially trained native medical service to provide the necessary medical attention in the native areas of the Union." We further expressed the opinion that "other regions in which the scattered population and the great distances which a doctor must travel to render service make insurance actuarily impossible might be provided for apart from the insurance scheme, but simultaneously therewith, by some form of subsidy somewhat on the lines of the Highlands and Islands arrangements in Scotland." The Commission expresses the same view, and recommends that in such rural areas steps should be taken to "extend the scope of the service by district surgeons and the provision of an increased number of tours" by such surgeons. It believes, justly, that this service is "considerably in advance of the arrangements made in many other countries where the same problem exists," and prints in an appendix the Highlands and Islands scheme, which, it states, "possesses features which are also to be found in the scheme of district surgeons," and which, with slight modification, might well be adopted in extending that scheme.

In our previous article we expressed the opinion that it would be impossible to exclude the "coloured people" from insurance, and highly undesirable to exclude the natives in industrial areas, and said: "It seems probable that the question of colour will be avoided by giving special consideration to the position of low wage-earners, including not merely natives and coloured people, but many of the class known as 'poor whites,' preponderantly low-class Dutch." The Commission says: "It would be undesirable to make any distinction on the grounds of colour in an insurance scheme. We are of opinion that employers of persons earning less than £35 per annum in insurance areas and who do not satisfy the authority that they are making adequate provision for hospital and medical treatment of such employees should be required to pay the whole contribution to the insurance fund, and in the case of persons in higher groups the greater part of the contributions" according to scale, the proviso extending to those earning not more than £60 per annum. This scheme, as we suggested should be the case, will "allow of the continuation of some existing provisions for medical and other benefits already working satisfactorily in connexion with railways and some mines."

The actual scheme of sickness insurance proposed follows, in the main, the lines of that established in Great Britain. There are, however, a few very important differences which must be considered, apart from those involved in what has already been noted. As regards the persons to be insured, employees engaged in agriculture in insurance areas will be excluded, and "employees earning over £400 per annum will be excluded without differentiation between manual and non-manual labourers." In Great Britain, it will be remembered, the income limit is £250 a year, and this applies to non-manual workers only. There is a case for a higher limit than £250 in South Africa, but, unless opinion has recently changed, the medical profession there has always declared that a limit of £400 is much too high. If some such limit as £6, or at most £7, a week is preferable, the profession should come to a speedy decision and should take active steps to secure its acceptance. The application of an income limit to the whole insured population, however employed, is extremely interesting. It has been demanded by the British Medical Association for Great Britain, but has always been declared to be administratively impossible; yet it still appears to be both logically and socially right. If the experiment be made in South Africa, and if it be successful, it will be of great value.

Another important difference between the proposed scheme and that now in operation in Great Britain is that (apart from low wage-earners) the contributions and the sick pay are not uniform, but are graduated according to wage groups, and, in the case of sick pay, to the number of dependants (wife, and children under 16 years of age, not exceeding four). In calculating these groups it is stipulated that "wages shall not be confined to substantive salaries or wages, but shall include all local and other subsistence allowances, cost of free quarters and board, and any other items in cash or in kind which may legitimately be included as part of the real earnings." Moreover, the definition of sickness is to be "inability to do his ordinary work by reason of the abnormal state of an insured's bodily or mental health, provided the insured complies with the doctor's orders or other instructions relating to his conduct while ill, and that the sickness was not caused by his own wilful misconduct"; and "an insured woman will be entitled to sick pay if she has to go off work owing to pregnancy; the maternity benefit is given in substitution of the sick benefit for the confinement and for a period of fourteen days subsequent thereto." Difficult as is the position with regard to the certification of "incapacity" under the scheme in Great Britain, it may be suggested that difficulties are not likely to be less under the proposed definition and conditions in South Africa. This is another point on which the profession in the Union might well make up its mind and offer guidance to the authorities. Correspondingly, the amount of maternity benefit varies in accordance with wage groups; but it is provided, contrary to the custom in Great Britain, that "in the case of a married insured woman whose husband is also insured, only one benefit will be payable on each confinement."

With regard to medical benefit, this will include "(*a*) ordinary medical benefit, for the insured, his wife, and

[1] Union of South Africa. Second Report of the Commission on Old Age Pensions and National Insurance. Government Printer, Pretoria. 7s. 6d.

dependent children under age 16, but no specialist treatment; (b) medical attendance during pregnancy of an insured woman or the wife of an insured man, but not for the confinement or for an illness during the period of fourteen days subsequent thereto; (c) medicines and curative appliances for the insured, his wife, and dependent children under age 16," but "an insured woman will be entitled to medical benefit in respect of her dependent children under age 16, but not in respect of a husband." Thus from the beginning, dependants of insured persons are to be included in the scheme; but, disappointingly, there is to be no provision for consultant or specialist service. In this connexion it may be noted, too, that there is no provision whereby additional benefits, such as dental and ophthalmic treatment, may be given, though it is remarked that "the time may come when it will be necessary for the people in South Africa to give serious attention to these points."

With regard to the provision of drugs and medical and surgical appliances, an important suggestion is made which, though differing from the practice in Great Britain, agrees with that of some European countries. In its summary of recommendations the Commission merely says that "any scheme which includes drugs and medicines as part of its medical benefit must make provision in its regulations for the control of excessive prescribing and unnecessary consumption of drugs," but in the body of the report it goes further and says: "The evidence as regards the increasing consumption of drugs when they are provided free is of such a convincing nature that we have no hesitation in recommending that on every occasion on which an insured person is supplied with drugs provision should be made whereby he would be called upon to make some contribution towards the cost of the drugs supplied." South African experience, indeed, seems to indicate that its people have an even greater liking for "a bottle of medicine" than those of other countries. Though general statistics are wanting or unreliable, yet "in one society the cost of drugs and medical appliances for the insured and his dependants was 20s. 1d. per member, or 6s. 8d. per recipient per annum. In another, which only paid a proportion of the bills, the cost to the society over six years ranged from 24s. to 41s. 6d. per member, or from 7s. 4d. to 13s. per recipient per annum"!

The cost of medical benefit for the purposes of the report (including, of course, the cost of medicines and appliances) is taken as 25s. per annum per family. The corresponding cost as prescribed by the Acts in Great Britain is a maximum of 13s. per insured person. This latter amount includes the cost of mileage and a portion, though a small one, of the cost of administration. It has been found very difficult in practice to keep within the maximum. There seems, in the report, to be some uncertainty as regards the cost of administering medical benefit. Under that specific heading the Commission says: "The fund should be debited with the cost of administration"; but elsewhere it says: "We recommend that the cost of administration of the insurance scheme should be borne by the State." The latter appears to have been of the nature of an afterthought or a final decision; clearly the administration of medical benefit should not be an exception to the general arrangements. In the matter of method or area of administration, this is not proposed to be through societies, but by a territorial system. Here, in connexion with the cost and administration of medical benefit, is clearly matter for thought and negotiation. The Commission recognizes this, and it is for the profession, again, at once to come to decisions and to open discussion with the Government or appropriate department of State.

A surprising feature of the proposed scheme is that in addition to these usual benefits—sickness, maternity, medical—there is included as an integral part of the scheme a funeral benefit. This is to be payable on the death of an insured person, his wife, or dependent child under the age of 16, and the amount of payment suggested is "about twenty times the daily basic wage calculated on the basic wage of the class in which the insured is placed for purposes of contribution." This would appear to be an unfortunate recommendation, unnecessarily loading and complicating the scheme, and it is difficult to understand why it is made. The only indication of a reason seems to be "the need for meeting a very great desire of the poorer classes," while all the statements of the Commission beyond this indicate that it is an illogical and irrelevant feature of a scheme for sickness insurance.

With regard to the matter of consultation with the medical profession in South Africa, the Commission mentions that it has on several occasions discussed with the Federal Council of the Medical Association of South Africa (British Medical Association) such subjects as medical benefits, services, and contract; and that it had the advantage of evidence from Dr. Brackenbury as to the working of the system in Great Britain. The Commissioners are evidently somewhat disappointed that they have not been able to obtain certain definite decisions from the Federal Council prior to making their report, and, as we have indicated, it is not unreasonable to expect some such decisions at an early date. Indeed, it is entirely to the interest of the profession that they should be made. It may be well to quote in full the paragraphs of the report in which the Commission refers to this need:

"We have on several occasions discussed medical contracts or some phase of this subject with representatives of the medical profession. We have so far not received the final and considered opinion of the medical profession on the subject, but it is not necessary for us to wait for this before reporting that we consider it is possible to formulate and work a scheme successfully in certain areas in South Africa. Such a scheme as we have suggested could be worked successfully, either by a system of panel doctors or by medical men engaged at fixed salaries. We consider that the medical profession should be interested in the scheme at the earliest possible stage, so that advantage might be taken of their wishes and experience in the promulgation and development of the scheme. Before the time arrives for Parliament to pronounce finally on the nature of the medical contracts we hope the profession will have been able to furnish the Government with their considered opinion on this and probably some of the other cognate points in which they are interested.

"Before a bill to provide a scheme of insurance against sickness is drafted we consider that a provisional agreement should be entered into with the medical and pharmaceutical professions, setting out the terms on which medical service and drugs will be supplied, so that Parliament might have before it the principal conditions under which the scheme is to be worked.

"In the course of these negotiations consideration should be given to the question of whether it would be advisable to insert a clause providing for means to eliminate unnecessary demands upon the time of the doctor and calls for trivial illnesses. If the insured persons have the right to enlist the services of the doctor for every trifling illness, the administrators of the scheme will have to recognize that this will take up so much of the doctor's time that he will be able to attend to a much smaller number of patients than would be the case if some form of restriction is adopted. The reduction of the number of patients on the doctor's list means, of course, that a much higher payment per head must be made, and that again involves higher contributions."

There is one further matter which all those who are interested in the immense development of social services in this country and their effect on such questions as migration within the Empire will be glad to see in the report of the Commission. It is that of reciprocal arrangements with regard to such services between different countries.

"In any bill that is drafted to deal with insurance against sickness we think provision should be made whereby, with the authority of the Minister, the administrators of such a scheme in South Africa may make reciprocal arrangements with the authorities administering similar schemes in other countries, by which periods of insurance, contributions paid, and residence in one country shall be treated as if they had been periods of insurance, contributions paid, and residence in that other country, and provision should also be made for the making of the necessary financial arrangements."

In concluding this notice of a report of very great value, interest, and importance to the medical profession, and to political and social students and workers, we may say with confidence that the British Medical Association, both in Great Britain and in South Africa, will wish to thank the chairman and members of the Commission, and will desire especially to associate themselves with the Commission in its acknowledgement and appreciation of the services of Mr. J. Collie, the distinguished civil servant who was the secretary of the Commission and is now the Commissioner of Pensions in the Union.

Ireland.

Obstetrics and Gynaecology in Dublin.

As in previous years, the greater part of the August issue of the *Irish Journal of Medical Science*, which is the official journal of the Academy of Medicine in Ireland, is devoted to the annual reports of the three great Dublin maternity institutions—namely, the Rotunda Hospital, the Coombe Hospital, and the National Maternity Hospital. The report of the Rotunda Hospital, which covers the twelve months ending October 31st, 1928, was published in May, and reference to it appeared in these columns on June 8th (p. 1053), when mention was made of the "record" low percentage morbidity rate which had been reached during the year under review. The valuable statistical details which this report contains are now made available for closer study. A melancholy interest attaches to the Coombe Hospital report for 1928, in that it was prepared by the late Master, Dr. Louis Cassidy, who died on October 27th; an obituary notice appeared in the *British Medical Journal* of November 10th (p. 783). In Dr. Cassidy's last report of this hospital he enumerated various clinical abnormalities which occurred in its practice during the year under review, and mentioned that the usual treatment adopted in the seven cases of uterine inertia encountered was to give one drachm of chloral hydrate in four ounces of milk per rectum. Six hours later the patient received 2 c.cm. of pituitary extract, divided into eight doses at twenty-minute intervals. If this had no effect, 0.5 c.cm. of thymophysin and 10 grains of quinine bihydrochloride were injected intramuscularly after a further two hours. It is added that in the occasional case in which the membranes are intact, or after the death of the infant, morphine is given in large doses. Ovarian residue was tried, but proved disappointing. In cases failing to respond to this treatment, even when repeated, Cæsarean section was performed if the foetus was in good condition and delivery by any other means appeared impossible. In conjunction with Dr. R. Stumpf, Dr. Cassidy supplied, as an appendix to his report, a note on the *x*-ray treatment of non-malignant cases in gynaecology. An attempt was made to determine whether it was possible to stimulate the functional activity of cells when dormant or absent, and also the degree of cure of inflammatory lesions which *x* rays could achieve. It is stated that in many instances the application of *x* rays to granulating surfaces promoted rapid healing; details are given of the apparatus and technique employed. Benefit was derived by this means in cases of dysmenorrhœa; splenic radiation cured menorrhagia and metrorrhagia in a large percentage of cases. In non-tuberculous inflammation of the adnexa and parametrium the effect of small doses of *x* rays was striking in some instances, the pain disappearing, the temperature falling, and the sleep and appetite improving. Success is also reported in cases of tuberculosis of the peritoneum and adnexa. Temporary sterilization ensued in six cases as an undesired effect, but normal menstruation returned in all the patients within two years. The third report—that of the National Maternity Hospital—is shorter than the other two, but of equal interest as regards clinical notes. The practical value of these three reports from the clinical and therapeutic points of view is very high. Also included in the August number of the *Irish Journal of Medical Science* are clinical notes on three cases—namely, incomplete rupture of the uterus, carcino-sarcoma of the ovary, and procidentia complicated by rectal prolapse in a nullipara.

Hospital Treatment in Northern Ireland.

The Ministry of Home Affairs in a letter to the Coleraine board of guardians states that the Ministry has had before it, in the minutes of proceedings of the board on July 20th, the notice regarding two proposals to send certain patients to the Coleraine Cottage Hospital; with reference to these proposals it points out that it has been decided that a board of guardians has no legal authority to send patients to an outside hospital, and pay for their maintenance therein, unless such patients are bona-fide inmates of the workhouse, having been sent there on account of destitution. It is added that if the accommodation in Coleraine Union Infirmary is insufficient or unsuitable for the treatment of poor people residing in the union, it is the duty of the board to make such improvements as will enable it to provide the necessary treatment. As, however, this is a matter which will take considerable time, and it is essential that the persons now requiring treatment should not be prevented from receiving it, the Ministry suggests that the rural district council should make use of its powers under Section 155 of the Public Health (Ireland) Act, 1878, and undertake the responsibility for maintaining these patients in the Cottage Hospital. In this connexion the Ministry points out that the council can only pay for maintenance and medical expenses, and not travelling expenses. In suggesting this course the Ministry states that it has in mind the urgent need of treatment for the persons referred by the dispensary medical officer, and does not wish it to be thought that the provision of medical treatment is a normal function of a rural district council. It is undesirable that there should be several bodies exercising similar functions, and with regard to medical treatment the Ministry considers that the board of guardians is at present the body primarily responsible. The clerk said the Ministry's interpretation of the law was that the guardians could not pay for the maintenance of dispensary patients at the Cottage Hospital. The rural council could come to an agreement with the hospital for the maintenance and treatment of dispensary patients. At a subsequent meeting of the council it was decided to inform the Ministry that the council was quite willing to conform with the Ministry's suggestion if the Coleraine Borough Council and Portstewart Urban Council came into line.

Public Health in Kildare.

Dr. J. A. Harbison, medical officer of health for the County Kildare, in the course of his first annual report, states that school medical inspection has been successfully inaugurated; the antituberculosis and infant welfare schemes have been revised and improved. A scheme of inspection of midwives has been instituted so as to ensure the best possible skill and attention being given. Sanitary inspection has been put on a more regular basis, and arrangements have been made for the collection of vital statistics. The adoption of the Notification of Births Act is mentioned as a forward step; further progress will be made, and Dr. Harbison looks forward to having a few more milestones on the road of progress before the next annual report is due. Kildare is an inland county with an area of 418,644 acres; the population at the 1926 census was 58,028. The county is divided into nineteen dispensary districts, each with a part-time medical officer, appointed under the Medical Charities Act to look after the sick poor of the district; this officer is also given at the time of his appointment the post of part-time medical officer of health for the district. The part-time system of sanitary inspection by officials without previous training, and with very meagre salaries, has not been found satisfactory in the scheme of co-ordination, and it is hoped, as a sufficient number of these part-time posts fall vacant, to replace them with a whole-time appointment. In this county, where the county medical officer of health is charged with duties under the Acts dealing with infectious diseases, maternity and infant welfare scheme, school medical inspection, inspection of midwives, and many other duties, there is not sufficient time to devote to the strict supervision of these part-time sanitary officers scattered over the county. Sanitary conditions on the whole in the county cannot be accounted as satisfactory. In Kildare town and in Naas efforts are being made to induce owners of houses adjacent to the sewers provided by the local authority to put in water-closets and connect them with the public sewers. Dr. Harbison remarks that where public authorities provide sewage systems for their communities with a view to reducing the possibilities of disease in that community, they have a right to demand that use shall be made of them for the community's sake. In those places where conservancy systems are tolerated constant enforcement of the Public Health Act is necessary.

Scotland.

Laboratory of the Royal College of Physicians of Edinburgh.

In the annual report for 1928 of the laboratory of the Royal College of Physicians of Edinburgh, the curator (Sir Robert Philip) remarks that the year has maintained the excellent record of the past in respect of the number and quality of workers and the results of their investigations. The researches of some of the workers have been signally recognized. Dr. W. O. Kermack has received from the Royal Society of Edinburgh the Makdougall-Brisbane Prize for the period 1926 to 1928 for his contributions to chemistry which were published in the society's *Proceedings* and elsewhere; Dr. C. G. Lambie has received from the Royal College of Physicians of Edinburgh the Lister Fellowship for the period 1926 to 1928 for his work on carbohydrate metabolism; William Blackie, laboratory assistant, has been awarded a Junior Greenfield Prize for histological work by the council of the Pathological and Bacteriological Laboratory Assistants' Association.

Researches in Progress and Completed.

Twenty-three investigators have been exploring pathological, bacteriological, chemical, physiological, and statistical problems. The series of experimental studies with a view to the standardization of tuberculin, initiated by the curator in concert with Professor T. J. Mackie, to which reference was made in the report for 1927, has been completed. Parallel observations were conducted by Dr. Donald Stewart on human beings and by Dr. R. S. Bogbie on guinea-pigs, the resulting figures being examined statistically by the superintendent (Lieut.-Colonel A. G. McKendrick, I.M.S. ret.) and Dr. Kermack in order to obtain the figure most likely to represent the true strength of an unknown tuberculin in terms of the standard. With the aid of a grant from the Medical Research Council, Drs. Lambie, Kermack, and Lieut.-Colonel W. F. Harvey have been engaged in investigating experimentally the action of parathyroid hormone on the structure of bone. A preliminary note of their results, which confirm those of Bauer, Aub, and Albright, was published in *Nature* (1929, vol. cxiii, p. 348). Aided by a grant from the council of the British Empire Cancer Campaign, Mrs. Dawson has commenced an investigation into the pathology of the breast, using the material from about four hundred cases specially selected and prepared by her husband, the late Dr. J. W. Dawson, over a period of seven years. A research on pneumonia in childhood, largely pathological, and based on the study of large paraffin sections of whole lungs, by Drs. C. McNeil, A. R. Macgregor, and W. A. Alexander, has been in progress for some time, and a series of papers on this subject is appearing in the *Archives of Disease in Childhood*. The bacteriological investigation of a considerable number of the cases was undertaken by Lieut.-Colonel W. Glen Liston, who is of opinion that Pfeiffer's bacillus is all-important in relation to acute broncho-pneumonia in children. An attempt was made during the recent epidemic to estimate the prophylactic value of vaccination against influenza; in all, 700 persons were inoculated. The results obtained are better than those obtained by McCoy and Meyer, but not so good as those of Duval and Harris. Dr. J. S. Fraser has continued his studies on the pathology of the ear. These include a study of the pathological anatomy of labyrinthitis; an examination of the histological conditions in two cases of leukaemic deafness; and a study of microtia and congenital atresia of the external acoustic meatus, which, in collaboration with Mr. G. D. D. Davis, he described at the Otological Section of the Royal Society of Medicine. As the result of the examination of tissues collected from fifty cases, Dr. J. P. Stewart has completed a study of the development and pneumatization of the mastoid process, together with the pathological, bacteriological, and chemical features of acute mastoiditis. Dr. G. H. Percival has been engaged in the study of biopsy material from various types of skin disease, in particular of the pathology of vesicle formation, and of idiopathic atrophy. Considerable progress has been made by Lieut.-Colonel Harvey and Mrs. T. D. Hamilton in the setting up of a "cabinet gallery of tumours," the preparation of the collection having involved an attempt at the logical classification of neoplasms in general. Researches on chemotherapy include work on the synthesis of compounds which might possibly possess antimalarial action, by Dr. Kermack, Dr. R. H. Slater (Carnegie Fellow), and Mr. T. F. Smith, who has a grant from the Department of Scientific and Industrial Research. Various experiments have been performed by Dr. Kermack and Mr. W. Leeper with a view to elaborating a simple method for the estimation of pepsin in stomach contents. Dr. D. N. Nicholson has been engaged in an inquiry into the presence of reducing substances in saliva. The results of a considerable amount of work on ultimate carbohydrate metabolism by Drs. Kermack, Lambie, and Slater have been submitted to the *Biochemical Journal* for publication. The data relating to 500 cerebro-spinal fluids which have been examined by the colloidal gold and colloidal gum benzoin reactions have been collected and discussed by Drs. Kermack and C. I. B. Voge. The work of Dr. Kermack and Mr. Spragg on the physical properties of Wassermann antigens, described in last year's report, has been continued and extended. Other short sections of the report deal with work on the precipitating action and capillary electric effects of benz-carboline derivatives; studies on the theory of sedimentation; studies in epidemiology; and a statistical inquiry regarding asthma. A list of nine papers published from the laboratory during the year is given.

The generous financial assistance again given by the Carnegie Trustees in connexion with the research department is gratefully acknowledged by the curator. In the reporting department the resources of the laboratory have been more heavily taxed than in any previous year, 14,316 reports having been issued. The number ten years ago was 4,312. Of the total during the year, 3,059 reports were histological, 2,280 chemical, and 8,977 bacteriological.

Dundee Doctors in the Sixteenth Century.

At a meeting of the Forfarshire Medical Association held recently at University College, Dundee, Dr. R. C. Buist read a paper on Dundee doctors in the sixteenth century. Dr. Buist said that in addition to a small group of Dundee doctors such as James Watson, Dr. Michael Durham, and Sir Hugh Herries, who had been in service with the Stuart kings or otherwise out of the burgh, there were over a score of men who as barber-surgeons, surgeons, or physicians could be traced in the Dundee records. By parentage and intermarriage they were closely associated with the mercantile and landed classes, and their relatives were found also in the Church and law. Several of them entered into the official life of the community as councillors, and many of them added much general commercial activity to their professional service or even occasionally became ordinary merchants. Records of the burgh courts showed many features of professional life in the co-operation of practitioners, arbitration as to disputed fees, payment of fees partly in kind and the custom of having fees assessed, agreed upon, and guaranteed at the beginning of attendance, the guarantor being, if necessary, compelled to pay. In some instances practitioners were ordained by the court to complete a cure, and in one case a surgeon was assoilzied in an action for negligence where the patient was taken to the Edinburgh surgeons after the Dundee surgeon had closed his attendance.

Relics of Robert the Bruce.

The late Professor D. Noël Paton, professor of physiology in the University of Glasgow, had in his possession a considerable portion of the famous collection of antiquities which belonged to his grandfather, Mr. Joseph Paton, who resided at Wooer's Alley Cottage, Dunfermline. Amongst these were certain relics of King Robert the Bruce, which it is proposed should be handed over to the kirk-session of Dunfermline Abbey. One of the relics is a portion of the skeleton of King Robert—namely, the metatarsal bone of the great toe. Dr. Gregory of Edinburgh, who superintended the reinterment of the remains after their discovery in 1818, gives the following interesting if whimsical

account of how this somewhat gruesome relic came to be preserved: "I took —— with me over to Dunfermline to assist at the resurrection. On our return to the inn at the Queensferry, he convinced me that he had not returned empty-handed by producing a metatarsal bone of King Robert, very little decayed. This he declared that he did not steal, but he must have received it knowing it to be stolen. However, as it was impossible by that time to restore it to its rightful owner, it remains with —— till King Robert claims it, and in the meantime I have put it carefully in a glass phial with a ground-glass stopper, and an explicit memorandum telling whose bone it is, and when it was stolen." Dr. Gregory does not disclose the name of the perpetrator of this outrage, but the phial, with its content, subsequently found a place in the collection of Joseph Paton at Dunfermline.

Edinburgh Deaf and Dumb Institution.

At the annual meeting and presentation of prizes in connexion with the Edinburgh Royal Institution for the Education of Deaf and Dumb Children, which has been in existence for 120 years, Dr. Logan Turner, consulting surgeon to the Edinburgh Royal Infirmary, in moving the reappointment of the directors and officials, remarked that it was a matter of common observation that the adult deaf person received little sympathy from those with whom he came in contact, but the deaf child always aroused deepest sympathy. He questioned whether the medical profession was doing all it might do to assist the child who was born deaf or who had acquired deafness before it had obtained the gift of speech. Were the teachers in an institution such as that receiving all the help they deserved to have? The difficulty was that the medical profession required a more accurate knowledge of the influences of deafness in the child, and the effects which these influences produced upon the organ of hearing. If the teachers could utilize knowledge of the causes and degrees of deafness it might be very serviceable to the child. Dr. Logan Turner suggested that there should be greater segregation of the completely deaf and the partially deaf.

England and Wales.

Health of the City of London.

THE square mile of the City of London—it is almost exactly a square mile within a matter of twenty acres—differs from all other urban areas in the conditions it presents to the public health administrator. It has the resident population of a small country town, but a day population equal to the total number of people who live in such cities as Leeds and Sheffield. It is one of the most ancient of towns, with its history preserved in the very configuration of its streets and lanes, and at the same time it is a hive of modern industry, with more than a thousand factories, with great markets through which food is distributed to vast populations, and with thoroughfares in which the traffic problem takes on its most crucial aspect. It has far and away the lowest birth rate of any town in the kingdom. The number of little Cockneys added to the population last year was only 82. A much larger number of births were registered in the City, but not of children belonging to residents. Similarly, although 665 persons died within the City boundaries, only 140 were citizens. The annual report of the medical officer of health, Dr. W. M. Willoughby, who was appointed in the middle of the year under review, following the retirement of Dr. W. J. Howarth, contains much curious information. The reader will learn that 464 out of 1,148 City buildings inspected were found to be infested with rats, mostly the black rat, a climbing animal, who outnumbers the brown rat in the City by three to one. One firm of rat-catchers caught 25,748 rats during 1928 by methods less pleasant to read about than those of the pied piper. More regret will be felt at the partial extermination of the City pigeons: 2,000 of the birds which have fluttered around the porticoes of St. Paul's and the Guildhall were captured and killed during the year. The bulk of the report is concerned with London markets—Smithfield, Billingsgate, and Leadenhall—and the measures taken to ensure purity of food supply. Samples of the milk arriving at Liverpool Street Station from country farms have been examined, and the City bacteriologist reports that the milk is remarkably clean as compared with what it was ten years ago. None of the 48 samples collected could be described as dirty, though 17 had a trace of dirt in the shape of a few black specks in the sediment. Four of the specimens contained tubercle bacilli, the other 44 were free. The total quantity of meat which passed through Smithfield central markets approached half a million tons, 72 per cent. of it from abroad, the greater part from Argentina. Dr. Willoughby reports that tuberculosis continues to be the most important disease in home-killed meat, and there is shown to be a considerable increase in the amount of tuberculous beef and pork surrendered in the markets. Surrenders and seizures of unsound food products in 1928 make rather impressive figures—908,000 lb. of beef; 354,000 of mutton, 107,000 of pork, 4,900 tins of milk, 3,000 tins of meat, 26,000 heads of furred and 53,000 of feathered game, 1,400 lb. of fish, only 56 lb. of butter, and not a single egg! For diseased conditions as distinct from unsoundness, 65,000 lb. of beef, 636,000 of mutton, and 220,000 of pork were seized or surrendered. At the riverside wharves 108 tons of food, mostly fruit and vegetables, were condemned. The cases of infectious disease in the City, formerly ravaged by plague, were principally 23 of diphtheria and 25 of scarlet fever. There were no cases of small-pox. On the register of notifications on the last day of the year there were 45 patients with pulmonary and 49 with non-pulmonary tuberculosis. With regard to the City atmosphere, a daily observation all the year round is made at noon at the Guildhall. The amount of impurity varies from half a milligram to five milligrams per cubic metre of air, the latter amount being recorded when there is fog. As another little sidelight on City conditions, it is reported that, during excavations for building at the corner of Seething Lane and Crutched Friars, human remains representing from 150 to 200 bodies were discovered, not presenting indications of orderly interment. They were given decent reburial at the City of London cemetery at Ilford.

Sewer Emanations and Public Health.

The commissioners appointed to inquire into the recent Holborn explosion recommended that any structure forming an underground cavity should be adequately and continuously ventilated. The proceedings at that inquiry led to some doubts being raised as to the adequacy of the ventilation of London sewers, for which the London County Council is responsible, and the reopening of the sewer ventilators wherever such a course seemed advisable was authorized. Unfortunately, the opening of these ventilators coincided with a period of drought, and the lack of rain sufficient to ensure proper flushing led to many complaints of smells from the sewers and a demand for the closing of the ventilators. Investigations at 325 open ventilators were made, and as a consequence 250 were closed, but, of course, the closing of any ventilator tends to increase the intensity of the emanations at the neighbouring openings. In a report on the subject the main drainage committee of the London County Council states that the matter of sewer ventilation is of great complexity, and has occupied expert opinion for eighty years. The ventilation of sewers has always been regarded as essential, both from the point of view of safeguarding the lives of the workers and the safety of the sewers themselves. Probably no scheme of ventilation can be considered satisfactory from all points of view, but in the opinion of the Council's advisers there is nothing to equal ventilation at ground level by manholes at proper intervals, though ventilating columns may be of value in special cases. A large section of the public, however, accepts it as a fact that sewer air is severely injurious to health and gives rise to fevers and the like. When the question was comprehensively investigated by the London County Council fifteen years ago the opinion of the experts who were consulted was that sewer air had no power of taking up bacteria from the sewage with which it was in contact, and that the micro-organisms in sewer air are related to those in the air outside, and not

to those of the sewage. Moreover, the main drainage committee points out, sewer ventilation has been in operation for an indefinite period, and apparently no outbreak of disease has resulted therefrom, while the men working in sewers, and in closest contact with sewer air, have an excellent record of health. It is difficult, the committee concludes, to accept the suggestion that serious health considerations are involved, though it is admitted that during the drought there was a measure of public inconvenience in certain localities. The difficulty is to reconcile popular opinion with the measures necessary for the safety of the sewers and the sewer men.

Liverpool Open-air Hospital for Children.

In his report for 1928, as senior medical officer of the Liverpool Open-air Hospital for Children, Leasowe, Dr. T. Hartley Martin deals briefly with the results of the use of artificial light in the new light department recently completed. All cases, he says, do well clinically on general irradiation with the exception of cases of disease of the spine, hip, and knee, complicated by sinus formation and albuminuria. Certain cases of tuberculous peritonitis of the miliary tubercle type, also, do not do well in young children. In cases of dactylitis, and disease of the carpus, metacarpus, tarsus, and metatarsus, there is marked improvement; while the results in the treatment of tuberculous adenitis after curettage by local irradiation with the mercury vapour lamp are startling. Researches by Dr. J. C. McFarland suggest that the failure of advanced cases of joint disease to react favourably is due to acidosis. In acidosis there is an inefficiency of the excretory function of the liver; and the inefficiency, Dr. McFarland thinks, is increased by light treatment. The records of the hospital show that about 85 per cent. of the tuberculous patients were discharged with the disease quiescent, and from 80 to 90 per cent. of these have remained so.

Freedom of Shaftesbury conferred on Sir Thomas Horder.

Sir Thomas Horder, Bt., who was born at Shaftesbury, Dorset, received on August 15th the freedom of this ancient borough; he lived there for only the first year of his life, his family then moving to Swindon, which, until lately, was regarded as his birthplace. Replying to the toast of his health at a luncheon given by the Mayor and Corporation of Shaftesbury, Sir Thomas Horder remarked that by a curious coincidence the first time he returned to the town for a consultation he was conducted to the house in which he was born in order to see a patient who was then residing there. The freedom of the borough was presented in the Guildhall, and Sir Thomas Horder, in expressing his thanks, commented on the influence which a birthplace might have on a man's character and success in the world. In this respect, he thought, some importance might be attached to maternal impressions as regards their influence on the unborn child. He believed that Shaftesbury, with its beautiful situation, had undoubtedly exercised a beneficial effect upon his life. He would, therefore, always value the privilege of being made a freeman of his native town.

General Lying-in Hospital, Lambeth.

The General Lying-in Hospital, Lambeth, which was founded in the year 1765, was incorporated by Royal Charter in 1830, when the present buildings were erected. For some time the accommodation has been quite inadequate, and it has been found necessary to contemplate a considerable extension. A fund opened for this purpose has already reached £18,000, but a further £22,000 is still urgently required; as previously mentioned in our columns, the premises must be rebuilt by 1930, according to the terms of the lease. In the annual report of this institution for 1928 it is stated that during that year 1,043 in-patients and 1,336 out-patients were treated, these figures representing increases of 36 and 93 respectively over those of the previous year. The total cost of each in-patient was £8 5s. 4d., and of each out-patient £1 0s. 3d. The patients contribute towards the cost of maintenance whenever this is possible, but necessitous cases are treated free. Ante-natal clinics are held daily at the hospital and its branches at Southwark and Camberwell, the attendances exceeding 12,000 annually; the children are supervised at the infant welfare centre until they reach the age of 5. It is also mentioned in the report that the maternal mortality rate for the ten years 1919 to 1928 was 1.6 per 1,000. For many years the in-patient treatment of the hospital has been associated with a training school for midwives and monthly nurses. During recent years the field for training has been considerably extended by including the out-patient department; a home for midwives and nurses has been provided in a separate building opposite to the hospital. Post-graduate instruction for midwives is also a feature of the work of the General Lying-in Hospital, and the sixteenth annual "week" was held last May. Lectures and demonstrations were then given, and visits were paid to other hospitals and maternity centres.

India.

The Pasteur Institute at Kasauli.

THE twenty-seventh annual report of the Pasteur Institute of India at Kasauli calls attention to the decrease in donations and contributions from all sources, except from the Government of India, during the twelve months ending June 30th, 1928. Treatment centres have now been established at Lahore, Rawalpindi, and Allahabad, as previously mentioned in the *Journal*, and consequently there has been a gradual decrease in the number of patients coming to Kasauli; against this, however, must be set the financial enrichment resulting from the increased sales of vaccines. Commenting on the position, Major R. H. Malone, I.M.S., who was one of the directors of the Institute during the year, remarks that no great economy can be made in the administration of the Institute without loss of efficiency; if the present sources of income cannot be further exploited, new sources must be brought into being. The first alternative is not considered practicable by him in view of the fluctuating but diminishing contributions from provincial Governments during the past ten years, and the fact that, as the novelty of an institution passes off, voluntary contributions gradually decline. On the other hand, there seems to him to be little doubt that the proceeds from the sales of vaccine might be substantially increased. A suggestion made ten years ago, and revived in 1927 by Lieut.-Colonel J. Cunningham, I.M.S., director of the Institute during the greater part of the time covered by the report, is that treatment might be charged on a *per capita* basis. Instead of appealing continually for contributions and donations, a fixed charge would be made for each course of treatment on an estimate calculated to cover the running expenses of the Institute. It is mentioned that such a scheme has been in operation at the Pasteur Institute in Bombay since its opening in 1922, and that it has proved to be satisfactory. The vaccine employed at the Kasauli Institute has been of two types—namely, the 1 per cent. carbolized vaccine used since 1912, and vaccines prepared by the new etherized method, which were tried in the most severely bitten cases. The death rate at Kasauli and the three other centres is lower than in the previous year. This is attributed to the greater efficacy of the etherized vaccine which is being used at Kasauli, and, in the case of the other centres, to the actual and relative decrease in the number of patients suffering from the most severe types of bite, the greater majority of such cases having been sent to Kasauli to receive injections with the new vaccines. No more treatment centres were opened elsewhere during the year, since the policy of the Institute in this respect will depend on the results of the investigation into the value of the etherized vaccine. This particular inquiry has been continued throughout the year under review, under the direction of Lieut.-Colonel Cunningham, the entire cost having been borne by a grant from the Indian Research Fund Association; a report will be published in due course. Various scientific papers by members of the staff have been published during the year in connexion with this study, which is being continued. Major Malone calls attention to the interesting point that the death rate of bitten

persons who come from the United Provinces is twice as great as that of those from the Punjab. There is no evidence that rabies is more prevalent in one province than in the other, and the number of patients is about equal in each case, the Institute being equally accessible to both provinces. He thinks that the people of the Punjab in general may be better acquainted with the danger attending such bites, and more convinced of the value of anti-rabic treatment, or less willing to take risks, than the people of the United Provinces. He suggests that the question will probably well repay further investigation.

South Travancore Medical Mission.

A vivid picture of the distress caused by a cholera epidemic and of the efforts made to cope with it is given in the annual report of the South Travancore Medical Mission for 1928. This Mission, which was founded ninety years ago, in connexion with the London Missionary Society, now owns fourteen hospitals and three dispensaries, as well as leper asylums for men and women, and the present report contains numerous details of special interest. A much-needed nursing home for Europeans was established at Neyyour in 1928, and the fees thus derived will assist the general work of the medical mission. Towards the end of 1927 the branch hospital at Santhapuram was destroyed by a storm, but during 1928 it was rebuilt on a more extensive scale, and is now in full working order; a considerable sum of money for its rebuilding has been obtained locally, and is an indication of the popularity it had won. Another branch hospital has just been completed at Kalyapuram on the main central road of Travancore. A large number of maternity cases are conducted by the mission staff in the villages near the hospitals, and in this way improved sanitary conditions are being introduced into many homes. The report contains photographs of some of the more unusual clinical conditions met with, including one case of very extensive fibrocystic disease of the jaw, and another of elephantiasis complicating a foot injury. Duodenal ulcer is said to be the commonest of all surgical diseases encountered, but the limited number of beds and attendants restricts the number of patients dealt with to about 230 annually. The opinion is expressed that this form of ulceration is a deficiency disease, partly due to the prevalent tapioca diet, and partly to the very hot curries containing inadequate quantities of vitamins, but popular with the local inhabitants. Seven out of every eight cases of duodenal ulcer, however, came from a small area of Travancore where fish is the chief vitamin-supplying article of diet. An inquiry into the etiology of this condition is in progress with the close co-operation of Colonel McCarrison at Coonoor. In most cases the shorter operation of gastro-enterostomy is preferred to the Billroth II method. Cancer of the jaw is also common; it has been found inadvisable to remove the teeth before an operation, owing to the frequency with which implantation growths occur in the tooth sockets. Laryngotomy is almost invariably used for mouth operations, and to this is attributed the fact that patients rarely develop pneumonia subsequently. Comment is made on the great change that has followed the introduction of hydnocarpus oil into the treatment of leprosy after many disappointing experiments with other forms of treatment. The preparation now used is pure crude hydnocarpus oil, to which is added 4 per cent. of creosote. The treatment of all associated diseases such as syphilis is conducted energetically, and attention is paid to the provision of good food and adequate exercise.

Public Health Work in Villages.

In the annual report of the Hygiene Publicity Bureau of the United Provinces for the year 1928, the assistant director of public health, Dr. A. Souza, describes a scheme for introducing improved health measures into isolated villages in India, which was first tried in the Lucknow district with very encouraging results and has subsequently been extended considerably. Special attention was paid to persuading villagers to store manure heaps outside their dwellings. Boys and elderly men were trained systematically to give first aid in accidents, to promote the maintenance of cleanliness in the houses and streets, to assist in securing more regular registration of births and deaths, and to distribute the medical remedies supplied by the dispensaries. Efforts are being made to establish small dispensaries in such villages on a co-operative basis, subscribers being given medicines at cost price, while non-subscribers are charged a little extra, the profits being handed over to the subscribers. The function of such dispensaries is to give first aid, to treat ordinary ailments, and to work in conjunction with the permanent district dispensary in the event of there being an outbreak of some serious disease. Many people in these villages do not know where to apply for help in a case of serious illness, and such information is now being broadcast by the smaller village dispensaries. As regards sanitation, attention is at present being directed particularly to the four chief infectious diseases of the United Provinces—namely, cholera, plague, malaria, and small-pox. Public interest is also being stimulated in matters pertaining to child welfare, school hygiene, and vital statistics. Circulars in connexion with the administration of this scheme for village dispensaries and public health education have been prepared and circulated in many districts in the United Provinces. It is believed that a valuable system is being developed which will help eventually to prevent the spread of diseases such as plague or cholera.

Correspondence.

METHAEMOGLOBINAEMIA.

SIR,—I was much interested to read in your issue of June 15th (p. 1070) that an authority of the standing of Professor J. S. Haldane considers methaemoglobinaemia to have been a possible cause of the "heliotrope cyanosis" met with as a very fatal complication of influenza during the pandemic of 1918.

That this possibility had been envisaged, and indeed excluded, in some cases of the condition may be gathered by a perusal of the following extract from an authoritative source:

"For a long time the nature and causation of this peculiar heliotrope cyanosis was obscure. It was certainly not due to circulatory or cardiac failure, for the condition of the heart and pulse remained strikingly good. At one time it was thought there might be some peculiar chemical change in the blood leading to the formation of methaemoglobin or even sulphaemoglobin, but repeated spectroscopic examination showed no abnormal blood pigment to be present . . ." (*Official History of the War.* Medical Services: Diseases of the War. Vol. i, pp. 181–182.)

Thus it would appear that methaemoglobinaemia was not the cause of the condition in those cases of heliotrope cyanosis in which spectroscopic tests of the blood were carried out.

In the section on cyanosis in French's *Index of Differential Diagnosis*, fourth edition, appears the following:

"Methaemoglobinaemia and sulphaemoglobinaemia are diseases which have been grouped together under the term *enterogenous cyanosis*. Both are exceedingly rare. The tint of the skin by itself suggests the diagnosis, being altogether different from that of ordinary cyanosis, and yet not to be mistaken for pigmentary affections such as Addison's disease, argyria, ochronosis, or haemochromatosis. There is no polycythaemia. The diagnosis is established by spectroscopic examination of the patient's blood. . . . Some cases arise without any obvious external cause, and are to be distinguished from those in which the blood changes are directly attributable to the effect of taking chlorate of potash, aniline derivatives, acetanilide, phenacetin, phenazone, and possibly other drugs. Some remarkable cases have occurred as the result of using brown boots polished with a preparation containing oil of mirbane, nitrobenzol, or nitrobenzene."

French thus distinguishes an endogenous or enterogenous variety of the condition, exceedingly rare, and unconnected with the taking of drugs or other external agents, and an exogenous form due to the ingestion or inhalation of certain drugs or poisons mostly of the aniline groups.

I believe, although spectroscopic tests are lacking, that I have seen recently an example of "enterogenous cyanosis" in a patient desperately ill with typhoid fever. Certainly in this case the cyanosis was of a violet or heliotrope colour, quite unlike that usually associated with cardiac embarrassment or ordinary anoxaemia, nor was the heart apparently unduly distressed. Foremost amongst the "exogenous" group mentioned by Dr. French, although not specifically included in his list, must be placed the new German synthetic quinoline derivative plasmoquine

(alkylamino-6-methoxyquinoline), which is receiving at the present time an extensive trial in the treatment of malaria in South America, India, and other endemic centres of the disease.

Unfortunately, toxic manifestations are all too commonly seen in patients undergoing treatment with plasmoquine, by far the commonest of which are cyanosis and abdominal pain; in fact, a certain degree of cyanosis, most marked in the lips, is almost the rule in patients under treatment with plasmoquine, and, although *per se* unassociated with any particular discomfort or immediate danger, constitutes a most valuable danger signal of intolerance to the drug, which should, in the opinion of most clinicians, immediately on its appearance, be withheld for a few days. This cyanosis has been shown by numerous observers to be due to partial conversion of the oxyhaemoglobin of the blood into methaemoglobin.

Thus Fischer and Weise (1927) found that methaemoglobinaemia could always be detected in 25 out of 26 patients a few days after the commencement of treatment, and they found, further, that the degree of methaemoglobin in the blood depended more on the degree of anaemia of the patient than the dosage of plasmoquine. (With this latter conclusion we cannot agree, for in our small series it was found that toxic symptoms—amongst others, cyanosis—were much more common in the case of patients under treatment with comparatively large daily doses of the drug (0.1 gram) than when a smaller daily dose (0.04 gram) was used.) The above two observers also concluded that it was the alkylamino group which was the cause of the methaemoglobinaemia, as in the case of acetanilide and phenacetin poisoning.

In our series the above two toxic symptoms of cyanosis and abdominal pain appeared with some regularity between the sixth and the tenth day of treatment, and, whilst comparatively common, as stated above, in patients receiving 0.1 gram daily (10 out of 17 cases), were also met with, although in a smaller proportion (7 out of 36), in those who received the much smaller dose of 0.04 gram daily; this suggests that personal idiosyncrasy to the drug is marked in certain cases, and it has even been suggested (Sinton and others) that racial susceptibility may play a part, the Northern European being apparently specially intolerant to any but the smallest doses.

That even susceptible individuals, if not too thoroughly poisoned by plasmoquine, may develop tolerance to its toxic manifestations is suggested by the following striking fact. If the drug be stopped directly cyanosis is noted or abdominal pain complained of, for one to three days, its readministration to complete the full course of twenty-one days, after this short break, has, in our series, been unattended, in all but a minority of cases, by any recurrence of toxic symptoms.

Unfortunately, cyanosis, at least in its early stages, is almost impossible to detect clinically in dark-skinned races, and in these we must be guided either by daily spectroscopic tests of the blood—a somewhat laborious proceeding and usually impossible in the field—or by the onset of the equally common and important early manifestation of abdominal pain, a symptom which must *never* be disregarded in patients undergoing plasmoquine medication.

A further interesting point arises. It is reasonable to predict that the fatal complication of heliotrope cyanosis will occur in future pandemics of influenza under similar conditions of "mass exhaustion" as it has occurred in the past, and is even now probably seen in isolated cases. If Professor Haldane's theory as to its causation, in spite of evidence to the contrary, be correct, we must be very wary in treating so-called "clinical malaria," which may turn out to be influenza, with a drug like plasmoquine, thus possibly adding an exogenous to an already developing endogenous methaemoglobinaemia. In any case I consider it safer, in view of the toxic nature of the drug, to reserve plasmoquine for the treatment of cases in which malarial parasites have actually been demonstrated in the blood, and in which other factors than malaria, either causative or contributory, can be reasonably excluded, reserving our old ally, quinine, for the treatment of "clinical" malaria and other cases of doubtful etiology.—I am, etc.,

S. SMITH,
Major, R.A.M.C.

Murree, India, July 17th.

TREATMENT OF PLACENTA PRAEVIA.

SIR,—The letter from Dr. D. C. Macdonald in your issue of August 10th (p. 278) requires an answer.

I have been to many discussions in different parts of the world, and I do not think I have ever been to one of greater value to the profession at large than that on placenta praevia, on July 25th, at the British Medical Association Meeting in Manchester. The number of speakers was great, and every aspect of the subject was amicably discussed. The meeting was ably conducted by an excellent chairman, who requested repeatedly that those who wished to speak should hand in their names. Why did not Dr. Macdonald do so? There was no "wrangle" about the pros and cons of Caesarean section, but obviously it was necessary to discuss them pretty fully at the present juncture.

While the *absolute* diagnosis of placenta praevia can only be made on vaginal examination, I always advise that, once ante-partum haemorrhage occurs, the case should be sent into hospital *without* vaginal examination being made. If the case is being treated at home, it is conducted as if it were in hospital.

Dr. Macdonald seems to have been particularly fortunate with ovarian residue. After a prolonged trial in a large number of cases, we were forced to discard it because of the absence of results.

Finally, Sir, I cannot end this letter without warning Dr. Macdonald to avoid applying forceps through an os "three parts dilated," especially in placenta praevia: he is courting disaster.—I am, etc.,

BETHEL SOLOMONS.
Master, Rotunda Hospital.

Dublin, Aug. 13th.

PREVENTION OF TUBERCULOSIS OF BOVINE ORIGIN.

SIR,—Some important conclusions emerge from the discussions reported from the Sections of Diseases of Children, Tuberculosis, and Public Health, at the recent Annual Meeting of the British Medical Association.

1. That the elimination of tuberculous animals from dairy herds is impracticable. (Savage, *Journal*, August 3rd, p. 203.)
2. That in spite of recent preventive measures (13,800 cows were slaughtered in 1928), there is still a widespread infection of the milk supply with tubercle bacilli in some areas. (McNeil, *Journal*, August 3rd, p. 194.)
3. That such infection, rather than decreasing, is slightly increasing. (McNeil. Kay Menzies.)

Answers to questions in Parliament have indicated:

4. That probably nearly 2,000 infants die of bovine tuberculosis each year, and that several millions sterling are expended annually in the treatment, convalescence, and after-care of the survivors.

It would appear that the strictly logical method of stamping out the source of bovine tuberculosis in cattle is likely to prove economically impossible, involving as it does frequent inspections and the slaughter of many animals. Moreover, the grade A and certified milks are priced far beyond the pockets of the poorer classes, who suffer from the maximum incidence of the disease.

The practical deduction must be that the problem of prevention must be approached from a different angle. All milk supplied to infants and young children should be sterilized. At present this is accomplished by two methods: pasteurization; and drying. One process exposes the milk to heat for at least thirty minutes; the other, at any rate the roller process of drying milk, takes only three seconds. The advantages of the short exposure are that very little damage, if any, is done to the vitamin C or to the soluble calcium, both of which have been shown to suffer from the prolonged method of pasteurization (Daniels and Stearn).

If a national policy is to be adopted for the prophylaxis of bovine tuberculosis, it is time that the expensive and unpractical method of attempting to eliminate tuberculosis in cattle was shelved. But before adopting the measure of employing sterilized milks, care should be taken to select a process of sterilization which involves the least damage to the essential elements of the foodstuff. It

would be disastrous if, in avoiding the Scylla of bovine tuberculosis, shipwreck should happen after all on the Charybdis of scurvy and rickets.—I am, etc.,

Bristol, Aug. 11th. FRANK BODMAN, M.B., M.R.C.S.

ULCER-CANCER OF THE STOMACH.

SIR,—In a leading article in the *Journal* of August 3rd (p. 209) there is a reference to my observations on the frequency of ulcer-cancer of the stomach, but the figure quoted, 6 per cent. of cases of cancer showing microscopic evidence of previous ulceration, is incorrect. My most conservative estimate in this connexion was between 15 and 16 per cent. (vide the *Proceedings* of the Cancer Congress, London, 1928). It was approximately 6 per cent. of excised ulcers which showed evidence of commencing malignancy—a very different matter.—I am, etc.,

Sligachan, Skye, Aug. 10th. M. J. STEWART.

"ACTIVATED" FLUORESCEIN IN THE TREATMENT OF CANCER.

SIR,—Much more evidence—theoretical, experimental, and clinical—seems to me to be needed before a new "cure for cancer" can be accepted in "activated" fluorescein. All substances "fluoresce" or give off "characteristic" radiations when bombarded with x or gamma rays, in a series corresponding with their atomic numbers; these rays are very "soft"—that is, they penetrate only a millimetre or so of water or tissue. That any substance has yet been found to be useful in "intensifying" treatment (as an "intensifying" screen intensifies diagnostic rays) remains to be proved, though many substances have been tested with this aim (copper, silver, arsenic, iodine, lead, potassium, etc.).

There are so many points open to question in the article published in the *British Medical Journal* of August 10th (p. 233) that I for one remain sceptical as to sodium fluorescein being to any practical degree the much-hoped-for treatment "intensifier." Dr. Mottram's experiments *in vitro* with sarcoma tissue are of interest, but his results, so far as they go, cannot be carried over to tumours in the patient with rapidly changing body fluids.

One surely might have expected some more definite physical, experimental, and clinical proofs that "these rays . . . exhibit a potent lethal action on malignant cells"—more, that is, than any other ionizing rays produced in the tissues—and that "the actual rays which are employed to kill the cancer cells are neither x rays nor radium rays, but a totally different ray, the nature of which is not quite certain, but is most probably a ray near the ultra-violet line of the spectrum" (Dr. Claude Gouldesbrough, *Daily Mail*, August 15th). But we have no such proofs afforded us. On the contrary, we have a number of confused and apparently erroneous statements. May I refer to a few?

1. What proof is there that fluorescein gives off specially strong secondary radiations (as with light rays) with only medium treatment x rays and the very hard gamma radium rays—not fluorescing with soft or very hard x rays?
2. If the "fluorescein rays" were all-important, and the x rays and radium rays were comparatively inactive, why was such a large dose of x rays given as a three-pastille dose (half-distance scale)? The statements that a "mild dosage" was given, a "three-quarters pastille" dose (skin scale), must lead many to think that only small x-ray doses were needed, whereas full erythema doses were given, and repeated three times at weekly intervals—in all, very large x-ray doses.
3. How is this to be reconciled with statements that the use of the fluorescein reduces the quantity of radium required?
4. Details of the eight cases of "apparent recovery" would be interesting; the "clinical details" refer chiefly to the first case treated, for which I see two explanations alternative to that adopted: it is impossible to irradiate equally a convex area 7 by 5 inches from a tube in one position, and newer or more actively growing parts of a tumour often respond more quickly to irradiation than the older areas.
5. All the conclusions (*a*) to (*e*) follow equally well from adequate irradiation treatment apart from fluorescein.

The healing of ulcers may perhaps to a slight degree be accelerated by simultaneous treatment with fluorescein, brilliant green, or other substances; and any substance so used may be heralded as a "new ray" used in cancer treatment. But to deny the efficacy of three full erythema x-ray doses within three weeks, and repeated, with "four to six months' continuous treatment," and then to claim that the results depend on a new "unknown ray" (and even when this ray is localized in the skin painted over a large tumour), seems to me to belong more to the realm of magic than to that of scientific treatment.—I am, etc.,

London, Aug. 17th. J. H. DOUGLAS WEBSTER.

POST-VACCINAL ENCEPHALITIS.

SIR,—In the *British Medical Journal* for August 17th (p. 324), Dr. Poston raises the question of an epizootic encephalitis amongst rabbits. It is an interesting fact that in May, 1918—that is to say, when the epidemic encephalitis of that year was abating and the great influenza epidemic that commenced formally in the June was brewing up—an account was given in the *Globe*, by Mr. Edmund Hallett of Hendon, of an "epidemic amongst rabbits" which had cost him then recently the loss of many young rabbits. Mr. Hallett inclined to the "belief that some form of paralysis attacks the head of the animal."

It is to be hoped that the atmosphere of prejudice which in 1918 attended and surrounded the discussion of so many subjects may gradually become as much clearer in medicine as in other spheres, and that the relation between epidemics and epizootics of influenza and encephalitis will be seen sanely and whole.—I am, etc.,

London, W.1, Aug. 17th. F. G. CROOKSHANK.

PHYSIOLOGICAL STUDY OF ASTHMA.

SIR,—It is a matter for regret that Dr. Eric Holmes, in his letter in your issue of August 18th (p. 324), does not mention what he considers is the true explanation of the asthmatic paroxysm instead of merely affirming that there were no grounds at present for the views I had advanced and explained in my letter of July 27th, as though my arguments were not worth answering.

But Dr. Holmes tells us that Drs. Brodie and Dixon "were dealing, not with clinical asthma, but with an experimental condition which resembled it very closely indeed. They would probably not deny, in theory, the possibility of rhythmical contraction and dilatation playing a part in the clinical condition . . . quite satisfactorily accounted for by other and directly observable factors." Now the essence of my one criticism is that the laboratory conditions were so different from the conditions of a patient in asthma that, however correct the interpretation of the experimental factors, as such, these factors do not apply to the clinical conditions, and do not satisfactorily account for the clinical conditions.

The view I hold is not "the possibility of rhythmical contraction and dilatation playing a part" only in the clinical condition, but that they alone quite satisfactorily account for the clinical condition, while continuous bronchial spasm cannot do so.

It is just thirty years since I put forward my clinical interpretation of the respiratory phenomena in an asthmatic paroxysm, and after Dr. Holmes's letter I was glad to read afresh the original contribution of Drs. Brodie and Dixon published four years later, but still find no sufficient grounds for altering my views after an inspection of the tracings. As Professor Dixon is still away from home in South Africa, I may be forgiven if I prefer to await his return to meet any argument he may do me the honour to advance against my interpretation of the clinical factors at issue.—I am, etc.,

Bristol, Aug. 19th. PATRICK WATSON-WILLIAMS.

CARE OF THE UNMARRIED MOTHER.

SIR,—I was much interested in Dr. R. A. Gibbons's plea for the unmarried mother (August 10th, p. 276). In York there is a sheltering home run by the district branch of the Diocesan Association for Preventive and Rescue Work. There are many maternity cases among the women and girls admitted to this home. Each is given ante-natal care until the time for her confinement approaches. Meanwhile arrangements have been made for her admission

to a maternity hospital, as the home is not equipped to undertake midwifery. Many have gone to St. Faith's Hospital, Leeds, others to the Diocesan Maternity Home in Hull, and others to the York Maternity Hospital or York Infirmary. Many return afterwards to the sheltering home, mother and child being looked after and cared for for some months. The sisters, whose work is beyond praise, are Church Army trained. The home is supported by voluntary contributions, and receives a grant from the Ministry of Health, through the corporation. I have records of ante-natal examinations in 150 cases, and as far as I know none of these mothers died in childbirth.

If the time ever came when an infants' home were attached to this sheltering home, it would be a beneficent work, because when the time comes for the mother to go out to work and the child to the care of a foster mother, things do not always go so well for the child. I presume this home is only one of many others run on the same lines, so that the "rarity of Christian charity" is not so great as some might think.—I am, etc.,

York, Aug. 14th. N. KEMP.

THE ADMINISTRATION OF SEDATIVES BY MIDWIVES.

SIR,—In reference to Dame Louise McIlroy's address, published in your issue of August 10th (p. 231), I am sure that many practitioners must feel that all primigravidae should have a sedative or an anaesthetic—or both. Yet the district nurses refrain from sending for medical aid because they fear censure from the county council, which seems to regard each call for medical advice as an admission of inefficiency. The unfortunate primigravida may struggle for hours, even rotating an occipito-posterior presentation, but so long as the perineum can be kept intact she becomes, we presume, in the eyes of the council, "one up to the nurse." This state of affairs is most unfair to the patients and also to the nurses, and one can only hope that Dame Louise McIlroy's words may somehow or other filter through into the council chamber itself.—I am, etc.,

Whitchurch, Aylesbury, Aug. 14th. J. C. RYDER RICHARDSON.

FEES FOR ATTENDANCE ON DIFFICULT LABOUR.

SIR,—Dr. Rhys Paton's letter in the *Journal* of August 3rd (p. 223) raises the vexed question as to whether the fees for attendance at the request of a midwife are adequate and proportional to the services rendered. I think it is a matter which the British Medical Association should reopen with the Ministry of Health, with a view to raising the fee by at least one guinea for attendance on a confinement.

It would appear, however, that your correspondent had not made himself familiar with the Ministry Circular No. 358 of December 20th, 1922, where it would have been apparent that the maximum fee allowable was governed by Sections No. 1 and 2; he would then have been saved the trouble of sending a bill of such magnitude to the authorities, who, however much they may have valued the services rendered, would have been unable to satisfy the auditors of the Ministry to whom we, as ratepayers, are indebted.

As the case was a midwife's case one presupposes that the Caesarean section was not performed in the patient's house, but was done in some suitable institution to which Dr. Paton is attached; one would like to know whether any question of fee for this service would have arisen if the patient herself had been responsible for the account; in other words, was the operation not performed in a voluntary hospital where no question of fee could arise, unless the institution possessed pay-beds?—I am, etc.,

Dudley, Aug. 6th. ALFRED W. WESTON.

CHARLES CLAY AND OVARIOTOMY.

SIR,—In the report of my opening remarks as president at the first session of the Section of Obstetrics and Gynaecology at the Manchester Annual Meeting, published in the *Journal* of August 3rd (p. 192), I am recorded as having claimed that "Charles Clay was the first surgeon to perform ovariotomy." This is an obvious error, and no doubt arose through the necessary condensation of the reports. What I said was, that "Charles Clay was the first to perform the operation frequently, that it was he who raised it from a disastrous experiment to a well-recognized surgical procedure, and that the term 'ovariotomy' was coined by Sir. J. Y. Simpson for Clay's operation. Moreover, much of the credit which was given to Spencer Wells by right belonged to Clay, as he was regularly and frequently performing this operation fifteen years before Spencer Wells did his first ovariotomy." I believe the other part of the statement to be correct, that "Charles Clay was the first surgeon to perform hysterectomy for fibroids."—I am, etc.,

Manchester, Aug. 14th. WILLIAM FLETCHER SHAW.

TONSILS AND ADENOIDS IN HOSPITAL PRACTICE.

SIR,—In the discussion on tonsils and adenoids in the Section of Diseases of Children (*British Medical Journal*, August 17th, p. 303), Dr. Scott Stevenson is reported to have said that the present method of removing tonsils and adenoids in the out-patient department of hospitals was a disgrace to British surgery. The meeting unanimously adopted a resolution condemning the practice and urging that children should be kept as in-patients under observation for forty-eight hours. With this resolution I agree most heartily, as will anyone who has anything to do with a nose, throat, and ear department.

The practice of treating tonsils and adenoid operations in the out-patient department has arisen from lack of accommodation of hospital beds, and we all agree that a great deal more accommodation is urgently required. But if we cease operating on these cases as out-patients pending the provision of beds our waiting lists are going to mount to unmanageable figures. And what is going to be the inevitable result? The very conditions for which we are advocating the urgent removal of tonsils and adenoids as a means of prevention are not going to be prevented. How many cases of otorrhoea are going to become chronic beyond hope of clearing up while on the waiting list? How many cases on the waiting list are going to develop acute mastoiditis from adenoids? How many glands in the neck are going to become definitely tuberculous? How many cases of diphtheria, acute tonsillitis, acute rheumatism, etc., are going to arise?

It is my practice, because of the non-existence of in-patient beds for these cases, to attempt to tackle all the children who present themselves for operation within a week of being seen in the out-patient department. Of course, it means a great amount of work in the week; but, so far, I have not had cause to regret it, and I certainly think it is preferable to admitting children for mastoid operations who are already on the waiting list for tonsils and adenoids. So long as the totally inadequate in-patient provision for these cases remains, there is something to be said for treating them as out-patients if only from the preventive aspect.—I am, etc.,

Hull, August 19th. R. R. SIMPSON.

THYROID AND MANGANESE TREATMENT.

SIR,—In the *Journal* of July 6th (p. 33) Dr. Langwill asks for reports of the results of the above treatment. I have given it an extensive trial in cases of chronic rheumatism and also in pneumonia.

The chronic rheumatic cases comprised all types—articular and non-articular. All the patients were thoroughly examined, and septic foci, when found, received appropriate treatment. A diet rich in vitamins was employed and carbohydrates were restricted; the state of suboxidation was combated by means of thyroid and manganese therapy. Various subsidiary measures—anodyne applications, massage, radiant heat, diathermy, ultra-violet rays, etc.—were employed in some of the cases for the relief of pain or the restoration of function.

The conclusions which one might draw from my series of cases are as follows: (1) Treatment evolved on the foregoing lines is of definite benefit to rheumatic patients. (2) While all credit cannot be given to the thyroid and manganese therapy, in view of the other measures employed, there is no doubt that in such cases it is of great value. It is more potent when employed as rectal injections of the permanganate solution with the oral administration of the thyroid substance; administered thus or orally in

cachets, the beneficial effect is more marked where a definite septic focus is found and treated. (3) There is little or no beneficial effect in cases of osteo-arthritis.

Since reviewing my series of cases I have treated many more, and have not found it necessary to change my opinion. After three to four weeks' treatment, say, in a case of rheumatoid arthritis, the patient has a renewed sense of well-being, and the increased range of movement and decrease of pain are remarkable. The earlier the treatment is employed, of course, the better, but it is really astonishing how many old bedridden cases improve and become able to move about and attend to themselves.

The anxiety usually attendant on the treatment of cases of pneumonia has, in my experience, been greatly reduced by the employment of the thyroid and manganese treatment. In three or four days from the commencement of the treatment, as a rule, the temperature, pulse, and respirations are normal; the lung is still consolidated and the sputum rusty, but the patient is feeling well and wondering what all the fuss is about. One patient, however, I remember, was delirious for two days after his temperature became normal. The treatment seems to be equally efficacious in lobar and broncho-pneumonia, and in adults and children. Some parents find it difficult to believe that their children are suffering from the much dreaded "pneumonia."—I am, etc.,

Milngavie, Glasgow, Aug. 11th. R. J. LESLIE FRASER, M.D.

THE NOISE NUISANCE.

SIR,—Adverting to your paragraph in the *Journal* of August 10th (p. 267), and to the drafting of the bill promoted by the Edinburgh Corporation, why should it be necessary to bring "within the meaning of the Public Health Acts" this requirement, that the noise shall be "dangerous or injurious to health"? Such a definition would assuredly enable many an offender to ride off with the easy avoidance which seems to have served Mr. Neville Chamberlain.

It is now forty years since I ceased to serve as a medical officer of health or to take part in public health administration, and, in the absence of any work of reference, I can only trust to a rusty memory. But my impression is that our forerunners did not hamper themselves thus when they framed such measures as the Town Police Clauses, under which emerged notices—still to be seen—for the prohibition of "street music" and other noises. The first three lines of the 33rd section of the Edinburgh Bill, as quoted in the *Journal*, seem to be excellently worded.

The scientific measurement of noise nuisance may be attainable when we arrive at the State of Laputa and our coats are cut by trigonometry. Until then, perhaps, we must be content to judge limits by their merits, as is done daily in our courts. At any rate, the point, if not already taken into account, may be worth consideration.—I am, etc.,

ARTHUR DOWNES, M.D.

Varengeville-sur-Mer, France, Aug. 11th.

Obituary.

WILLIAM EWART, M.D., F.R.C.P.,

Senior Consulting Physician, St. George's Hospital.

MANY St. George's men, now long established in practice, will feel that one of the last links with their student days has been broken by the death, on August 11th, in St. Mary's Hospital, of William Ewart, after some years of increasing disability.

He was born in London on December 26th, 1848, and educated at the University of Paris, where he took the degree of Bac. ès Lett., and medically at St. George's Hospital, entering the Medical School in 1869. The fifth volume of the *St. George's Hospital Reports* contains "Notes taken in a German Feld-Lazarette by W. Ewart, Esq. (student of the hospital)," showing that in September, 1870, during the Franco-Prussian war, he was at Mouzon working in a wool factory crowded with looms and wounded; he described how he performed Carden's amputation through the knee-joint, and stated that the application universally used for the wounds was carbolic acid, though "a dressing of camphorated wine, or alcohol and water, was sometimes substituted when the granulations assumed a spongy, flabby character." He added that in most instances the German surgeons showed great reluctance to operate; "they were always anxious to give unaided Nature her last chance, by which they often seemed to deprive the patient of his." Qualifying in 1871 at the College of Surgeons of England and obtaining the licence of the Royal College of Physicians of London in the following year, he was house-physician at St. George's Hospital, and then, on October 1st, 1873, entered at Gonville and Caius College, Cambridge, where he was a scholar from 1875 to 1880, and took a first class in physiology in the Natural Sciences Tripos of 1876. During part of this period—namely, from November, 1875, to December, 1876—he was house-physician at Addenbrooke's Hospital, being succeeded by Sir James Kingston Fowler. The Thruston Prize at Caius was awarded to him in 1880. After taking his degree he returned to St. George's Hospital and held a number of teaching appointments in the Medical School and the curatorship of the museum, which carried with it the performance of all the post-mortem examinations. At this time he became assistant physician at the Hospital for Consumption and Diseases of the Chest, Brompton, where he was also pathologist. In 1882 he proceeded to the degree of M.D. at Cambridge, and was successful against the late Sir Isambard Owen in a contest for the assistant physiciancy at St. George's Hospital, and accordingly resigned his appointments at the Brompton Hospital, as at that time it was not considered right to hold any other hospital appointment that occupied the afternoons. Five years later, on Christmas Day, 1887, he became full physician, and held this for the statutory period of twenty years, becoming consulting physician in 1907, the year in which he gave the introductory address at the hospital, on October 1st, "Res medica, res publica; the profession, its future work and wage." He was for years physician to the Belgrave Hospital for Children, and attached to several other hospitals as a consultant. At the Royal College of Physicians he became a member in 1874, three years before he took the M.B., and was elected a Fellow in 1881, giving the Goulstonian lectures in the following year on "Pulmonary cavities, their origin, growth, and repair." He was an examiner in medicine (1894–97), a councillor (1901–3), and a most constant attendant and not infrequent speaker at the College comitias.

Ewart was an indefatigable clinician, his ward visits being extremely conscientious and made with the greatest regularity; it was, perhaps, not without a hint of humour that he occasionally extended his round to the surgical wards to study the medical cases there. In his younger days he worked much at morbid anatomy and its clinical correlations, as is shown by his Goulstonian lectures and his atlas on the *Anatomy of the Bronchi and Pulmonary Blood Vessels* (1889). In this connexion it may be mentioned that in the Section of Tuberculosis at the recent meeting of the British Medical Association at Manchester, Dr. Maurice Fishberg, in opening the discussion on apical and subapical tuberculosis of the lungs, paid a tribute to Ewart's pioneer work in 1882, showing that "the so-called apical lesion" is much below the apex in many cases. A little later, turning his attention to the heart and pericardium, he spent much time in making flimsy tracings of the chest, and brought out a number of small books: *Cardiac Outlines* (1892), *How to Feel the Pulse and What to Feel in it* (1892), *Symptoms and Physical Signs* (1892), and *Heart Studies, chiefly Clinical* (1894). An expert in percussion and auscultation, some of his diagnoses were wonderfully accurate. On other subjects he wrote widely, such as *Gout and Goutiness* (1894), on bronchitis and bronchiectasis in both editions of Allbutt's *System of Medicine*, and a number of climatological reports on the southern counties of England in the two volumes of *The Climates and Baths of Great Britain*, brought out by a committee of the Royal Medical and Chirurgical Society in 1895. At the meetings of medical societies he was a frequent speaker, and was at one time president of the Chelsea Clinical Society. He examined at the Universities of Cambridge and Durham, and took the

ad eundum degree of M.D. at Durham in 1895. In 1908-9 he was chairman of the Westminster Division of the British Medical Association.

Mentally he showed considerable originality, and was prolific in hypotheses, especially about treatment—for example, of bronchiectasis, leukaemia, renal dropsy, and enteric fever. Thoroughly in earnest, he had a vein of distinct eccentricity, which with some disregard of practical details may explain why his early promise was never fulfilled, and he was, in spite of incessant application, denied popular success as a consultant. With courtesy of a kind now old-fashioned, he was a sensitive soul, but nearly always preserved an unruffled aspect where others might well have shown annoyance. Though once engaged, he never married, and led a somewhat solitary life; thus, especially in his later years when sadly crippled by rheumatism, he became a very pathetic figure. He was a devout Roman Catholic, and outside his profession his chief interests were musical. Since 1900 he had been a member of the Athenaeum, where for some years he had spent most of his time. H. R.

We are indebted to Sir WILLIAM H. BENNETT for the following appreciation:

The death of William Ewart will have aroused in the minds of a generation of St. George's men feelings of deep and affectionate regret, mingled with recollections of many pleasant hours spent with him in the wards of this hospital. Indefatigable in his work, he was an enthusiastic teacher, sparing neither time nor trouble in conveying the essence of his knowledge and experience to those who were ready to learn. An afternoon spent with him in the wards afforded a liberal education in intensive clinical investigation and diagnosis. The obvious, however clear, was not sufficient for him; he was always searching for something beyond with a persistence and attention to detail which, to those unaccustomed to his methods, seemed remarkable. Not content with methods of treatment and diagnosis as he found them, he was unending in his efforts to find something better with an eagerness which was irresistible. By nature an optimist, he approached every problem with a cheery confidence which was as stimulating as it was helpful. The large amount of time devoted to the hospital work which he loved so well, to the serious exclusion of outside interests, militated somewhat against his achieving the degree of popular success in the practice of a consulting physician to which, by his high attainments, he was entitled, and which, in ordinary circumstances, he surely would have attained. The name of William Ewart will be ever held in grateful memory by all St. George's men.

Dr. GEORGE NICOL HENRY, who died after two days' illness, on July 23rd, in his 68th year, was born in Banffshire, and graduated M.B., C.M.Aberdeen, with honours, in 1885. After holding the posts of medical officer at the County Asylum, Prestwich, he commenced practice in Kennington, S.E., forty years ago. For thirty-six years he was surgeon to New Scotland Yard and the "L" Division of the Metropolitan police. He was vaccinator and surgeon at Peel House in connexion with police recruits, but relinquished these appointments two years ago on reaching the age limit. For twenty years he was *medical officer to the Licensed Victuallers' School, up to* the time of its removal to the country. Dr. Henry was a member of the British Medical Association and also of the Medico-Legal Society and the Metropolitan Police Surgeons' Association. He leaves a widow, a daughter, and four sons, the eldest of whom is in the medical profession.

The following well-known medical men have recently died: Dr. GUSTAVE HUMBERT, professor of medicine at Geneva, aged 54; Dr. LOUIS LEJEUNE, professor of radiology and electrotherapy at Liège; Dr. GUINON, an eminent Paris physician and officer of the Legion of Honour; Dr. BENNO CREDÉ, a Dresden surgeon, aged 80; Dr. PICHLER, who was for many years editor of the *Wiener Klinische Wochenschrift*; and Dr. GEORG KASSNER, professor of pharmaceutical chemistry at Münster.

Medico-Legal.

FEES OF MEDICAL WITNESSES.

THE litigant's right to ensure the attendance of a medical witness by serving him with a subpoena together with conduct money was strongly emphasized by Judge Gwynne-James at Bath County Court on August 15th, when he fined Dr. Malone of the resident medical staff at the Royal United Hospital two guineas for failing to answer a subpoena to attend and produce the medical record of a person who had been a patient at the hospital.

Dr. Malone told the judge he had not appreciated what a subpoena meant. His honour proceeded to define the position of a medical man when subpoenaed to give evidence, and gave two instances of medical men refusing to give evidence in his court on behalf of their patients unless they were paid a special fee. One had demanded a special fee of twenty guineas. Such a demand, as the judge pointed out, is of no avail, and cannot be enforced. All a litigant has to do is to serve a medical man with a subpoena, together with proper conduct money, which is in the nature of travelling expenses to and from the court, and an extra payment of one guinea, "which may, in an exceptional case, be increased not beyond five guineas." The medical witness had no right to demand a special fee. If he did not obey the subpoena he committed contempt of court, and was liable to a fine, and even to imprisonment, if it were shown that he was openly flouting the authority of the court.

The *Daily Telegraph*, on August 17th, published reports of interviews with Dr. G. C. Anderson, deputy medical secretary of the British Medical Association, and Sir Bernard Spilsbury, who is constantly appearing as an expert witness in civil and criminal courts. Dr. Anderson referred to the protest sometimes made by medical witnesses before they are sworn that they have not yet received a fee for attendance. Such a protest is always advisable. It may be the effective cause of the exercise of the court's discretion to allow a witness a fee of from one to five guineas. As Sir Bernard Spilsbury pointed out, if a doctor fails to come to an agreement regarding a fee before he goes into the witness-box, he will be obliged to accept such fee as the court may allow.

A clear distinction, however, should be made between the position of the medical witness who is giving evidence as a witness of fact—an example being a medical practitioner giving evidence as to the condition of a patient he has been attending professionally—and the medical witness who is giving the court the benefit of his opinion as a medical expert upon a certain set of facts already before the court.

A subpoena is issued to compel the attendance of witnesses without whose assistance the material facts of a case cannot be presented to the court. Such a remedy ensures that justice shall be done. A subpoena ought never to be issued to compel an expert to give evidence as to his opinion upon a certain set of facts which have already been given in evidence by other witnesses. Such expert witness is, of course, entitled to a special fee, the amount being a matter of arrangement between him and the litigant who desires to call him.

STATUS OF AN UNREGISTERED PRACTITIONER.

THE London Sessions Bench, on August 10th, allowed the appeal of Lieut.-Colonel John William Kynaston against an order made under the Probation of Offenders Act, 1907, by Mr. H. L. Cancellor, at Marlborough Street Police Court, dismissing an information by the Royal College of Surgeons of England for wilfully and falsely using the title of "M.R.C.S. Eng.," implying that he was registered under the Medical Act, 1858.

Lieut.-Colonel Kynaston obtained the diplomas of M.R.C.S. and L.R.C.P. in 1885, but his name was removed from the *Medical Register* penally in 1922 in circumstances set forth in the police court and High Court proceedings, reported in this column on August 10th, 1929 (p. 281).

Lieut.-Colonel Kynaston's contention was that the use of the letters "M.R.C.S." after his name implied that he was a properly qualified medical man, and did not imply that he was registered under the Medical Act. It was common ground that Lieut.-Colonel Kynaston could continue to practise medicine, though he was not now on the *Medical Register*.

The chairman (Mr. Wilberforce), in allowing the appeal, said the Bench was agreed that Lieut.-Colonel Kynaston obtained the diploma of M.R.C.S. subject to the conditions laid down by the body which granted it, and, just as the

Royal College of Surgeons were able to give it, so they were able to take it away. But the question for the Court was, whether Lieut.-Colonel Kynaston's conduct in continuing to use the title "M.R.C.S." was wilful or false within the meaning of Section 40 of the Medical Act, 1858, and the court was of opinion that such a matter should have been tested in a civil and not a criminal court.

The order was thereupon set aside, but no costs were allowed.

THE NEW VACCINATION ORDER.

THE Ministry of Health has issued this week to boards of guardians a circular, No. 1025*a*, with reference to a new Order (Statutory Rules and Orders, 1929, No. 640) which the Minister has made under the Vaccination Acts. The purpose of the Order, which will come into force on October 1st, is to give effect to the first four recommendations printed at page 201 of the report of the Committee on Vaccination presided over by Sir Humphry Rolleston (Cmd. 3148. H.M. Stationery Office, 1928. 7s. net.) An account of the findings of the Rolleston Committee appeared in the *British Medical Journal* of August 11th, 1928 (p. 266), and further reference to them was made in our issue of June 29th, 1929 (p. 1174). The recommendations dealt with in the new Vaccination Order are as follows:

(1) In place of the officially advocated four insertions, trial should be made of vaccination and revaccination in one insertion with a minimum of trauma, and that multiple scarification and (or) cross-hatching be deprecated.

(2) Primary vaccination should be performed in infancy, between the ages of 2 and 6 months as at present, and revaccination be offered at the time when a child enters school (6 to 7 years), and again on leaving (14 to 16 years).

(3) Vaccination in multiple insertions should be available for such persons as desire to obtain the maximum protection against small-pox obtainable at one operation.

(4) In public vaccination parents should be informed that if, in consequence of vaccination, a child requires medical attention, it is the duty of the public vaccinator concerned to provide such attention without cost to the parents.

In the new Order effect is given to recommendations (1) and (3) by altering the present instructions to public vaccinators and the forms of vaccination contract. In future a public vaccinator should vaccinate or revaccinate in one insertion only, unless it is desired to obtain additional protection against small-pox at one operation, when the number of insertions may be increased up to four. The aim should be to obtain successful vaccination with the minimum of injury to the tissues, and in no circumstances must the vaccinated areas be cross-scarified or cross-hatched. In compliance with recommendation (4) changes are made in the Form of Notice of the requirement of vaccination given by registrars of births and deaths, in order that parents or guardians may be informed that, if vaccination is performed by a public vaccinator, it will be his duty to attend and prescribe such treatment as is necessary without charge to the parent or guardian, if in his opinion the child needs medical treatment in consequence of the vaccination. A new paragraph has also been added to the Form giving effect to recommendation (2), and authority is given to a public vaccinator to revaccinate any person who applies to him without reference to the period which has elapsed since the last vaccination.

The circular draws attention to the remarks of the Rolleston Committee, at page 200 of its report, on the occurrence of cases of "post-vaccinal nervous disease." The committee pointed out that, however seldom such cases might occur, they were of serious import, and could not fail to have an effect on vaccination both in its administrative and in its purely medical aspects. But the report also pointed to the extreme rarity of such manifestations, particularly after revaccination and after primary vaccination in early infancy, and the committee concluded that early infancy remains the time of choice for primary vaccination. The Minister recognizes that "post-vaccinal nervous disease," both in this country and abroad, has occurred mainly in children of school age or adolescents who had never previously been vaccinated, and that this fact emphasizes the desirability of securing the successful vaccination of infants. Where this has not been attained, the question which arises is whether it is advisable to vaccinate children of school age or adolescents. The Minister is of opinion that, in the present state of knowledge, and so long as the small-pox prevalent in this country retains its present mild character, it is not generally expedient to press for the vaccination of persons of these ages who have not previously been vaccinated, unless they have been in personal contact with a case of small-pox or directly exposed to small-pox infection.

Copies of the new Vaccination Order, with its two schedules of instructions, and of the Ministry's circular, will be furnished to all public vaccinators.

Universities and Colleges.

UNIVERSITY OF LONDON.

AN ordinary convocation will be held on Tuesday, October 8th, at 5.30 p.m., to fill the vacancy in the Chancellorship caused by the death of the late Earl of Rosebery.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

The following scholarships have been awarded during 1929–30:

University Scholarship (£100): John Bishop Harman. Entrance Science Scholarships (£150 and £60): (1) C. J. Cobbe; (2) S. H. Alavi and R. M. R. Belsey. William Tite Scholarship (£25): H. R. B. Norman.

The Services.

TERRITORIAL DECORATION.

THE King has conferred the Territorial Decoration upon the following officers of the R.A.M.C.(T.F.): Majors P. E. Barber (ret.), G. H. H. Waylen, M.C., W. George, M.C., and A. H. Fullerton and Captain J. B. McGovern (ret.).

Medical News.

THE annual dinner of past and present students of St. Mary's Hospital will be held at the Trocadero Restaurant, W., on Friday, October 4th, at 7 o'clock, with Sir John F. H. Broadbent, Bt., in the chair.

As will be seen from our advertisement pages the Royal College of Physicians of London invites applications for the office of Milroy Lecturer for 1931. The course, which consists of three lectures, will be delivered on Tuesdays and Thursdays in February or March, 1931. A copy of Dr. Milroy's "Suggestions" on the subject of his bequest, and information as to the emolument, may be obtained from the Registrar, Dr. Raymond Crawfurd, to whom applications must be sent by September 30th.

THE Fellowship of Medicine announces that the Brompton Hospital will hold an all-day course in diseases of the chest from September 9th to 14th; facilities will be given for attending the practice of the various departments of the hospital, and the instruction will include lectures and demonstrations. A course at the Infants Hospital from September 9th to 22nd is intended particularly for those engaged in infant welfare work; visits will be paid to other centres in addition to clinics held at the hospital. From September 10th to October 5th a course of lecture-demonstrations in psychological medicine will be given at the Bethlem Royal Hospital on Tuesday and Saturday mornings. There will be an intensive course of instruction in medicine, surgery, and the specialties at the Westminster Hospital, open to men only, from September 16th to 28th; the daily sessions will continue from 10.30 a.m. until 5.30 p.m. The Prince of Wales's Hospital and the North Middlesex Hospital will hold a course in medical and surgical gastro-enterology from September 30th to October 4th. The Metropolitan Hospital will conduct its first course under the auspices of the Fellowship in medicine, surgery, and the specialties from October 21st to November 2nd. The Fellowship has arranged a second evening course for the M.R.C.P. examination consisting of sixteen lectures; these will be delivered on Tuesdays and Fridays at the House of the Medical Society, 11, Chandos Street, Cavendish Square, from October 15th to December 6th. Detailed syllabuses of the above courses, and information regarding the general course arranged by the Fellowship in connexion with its associated hospitals, also copies of its *Journal*, are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A NEW course of post-graduate lectures will be given in the Manchester Royal Infirmary on Tuesdays and Fridays from September 24th to December 10th. The Friday lectures will be especially devoted to the explanation of recent scientific work and to other problems of interest. The lectures are free, and full particulars can be obtained from the secretary for the post-graduate lectures at the infirmary.

No. 55 of the Ministry of Health's Reports on Public Health and Medical Subjects is published to-day. It is a report by Dame Janet Campbell, M.D., on the English part of the international inquiry into infant mortality instituted by the Health Organization of the League of Nations. The investigation was carried out in four selected districts in this country in 1927–28—namely, Sunderland and parts of Staffordshire, where infant mortality was relatively high, and in Croydon and Oxfordshire, where it was relatively low. Copies of this report, which we hope to comment upon in an early issue, may be obtained from H.M. Stationery Office, price 1s.

ESTERS of morphine and their respective salts, and any preparations, admixture, and extract containing any of the said esters, are in future to be subject to Part III of the Dangerous Drugs Act.

LORD EBBISHAM (Lord Mayor of London, 1926-27) has become the treasurer of Dr. Barnardo's Homes in succession to the late Mr. Howard Williams.

Dr. L. MEREDITH DAVIES, medical officer of health for Northamptonshire, has been appointed medical officer of health for Devon.

LISTS of medical practitioners serving as members of local authorities or their subsidiary bodies in Great Britain have been published in our columns during recent months. We learn that Dr. J. F. O'Meara has been a member of the Town Council of Walsall for many years and is now an alderman; he has served on the Health Committee and Child Welfare Committee throughout his membership of the Town Council.

ACCORDING to Professor Roffo, the Argentine authority on cancer, the increase of cancer in Buenos Aires is shown by the fact that in 1890 there were only 308 deaths registered as due to that cause, a proportion of 18.76 for every 1,000 deaths, as compared with 2,179 deaths from cancer in 1928, or 81.5 per 1,000 deaths.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

"PERMANENT WAVES."

"L." inquires if there is any disadvantage to the hair from the hairdressing procedure of "permanent waving," and whether the waving can stand the ordinary amount of brushing and occasional washing. It is stated that the effect lasts six or eight months.

BLISTERING WITH SCARLET-RED.

DR. W. L. PEACOCK (Uganda Medical Service) writes: In reply to "R. V." (August 17th, p. 330), I suggest that the cause was a dispenser's error, and that biniodide of mercury was supplied, since this is both scarlet and blistering.

TREATMENT OF SEVERE HEADACHE WITHOUT PHYSICAL SIGNS.

DR. BLANCHE A. M. HENDERSON (West Hartlepool) writes: Perhaps "M. B." would like to try the following. At the onset of the headache let the patient lie in a hot bath for ten or fifteen minutes; perfumed bath ammonia may be added with advantage. Then the patient should take one tablet of veramon, followed by hot tea. Repeat this four-hourly as required. Some *patients do better on aspirin, grains 15,* also followed by either tea or hot water. "T. H. H.'s" patient might improve on a long course of bromide, conveniently given in the preparation sedobrol. Such patients enjoy this treatment.

INCOME TAX.

Deduction for Rent, Light, Coal, etc.

"W. C. A." inquires what is the usual proportion allowed for income tax purposes of such general charges as "rent (or annual value), rates, light, coal, repairs, servants, etc."

*** By law the proportion is within the discretion of the commissioners responsible for the assessment, and must not exceed two-thirds unless in a particular case "the commissioners are of opinion that having regard to all the circumstances some greater sum ought to be deducted." Putting aside for the moment the question of servants' wages, general charges varying with the size of the premises are frequently dealt with on the basis of half-and-half, or, where the rent includes some special element of site value for professional purposes, two-thirds to the practice and one-third to the domestic side. Some aid to testing the reasonableness of a proposed basis is to see what amount it will leave as a domestic charge. It should be borne in mind that the ground floor is the most valuable part of the premises, and that the garage should be covered by the professional portion of the total charge. The proportion for servants' wages varies very much with individual circumstances. The fact that a waiting-maid must be kept does not justify charging the whole of her expenses to the practice if in fact an appreciable part of her time is spent in private household work.

Expenses Incurred by Assistant.

"ASSISTANT" uses a car and motor cycle for professional purposes; the car is his, but he did not buy it.

*** Assuming that he is required to find his own means of locomotion, in which case the salary, etc., received and assessed will presumably be higher than it otherwise would have been, "Assistant" is entitled to deduct out-of-pocket expenses for garaging, running, and maintaining the car and cycle, and also an allowance at, say, 20 per cent., for depreciation. That allowance should be calculated at the value of the car as at the commencement of the financial year for which the claim is made. Licence and insurance expenses can be deducted, but if the car or cycle are used for private as well as for professional purposes some deduction will have to be made from the total claim in respect of the former use.

Earnings of Assistant.

"J. H. B. L." acted as house surgeon without salary from April to October, 1928, and as assistant in general practice from that time to April, 1929. He earned £136 in that period, and has been assessed at £50 gross for the financial year 1928-29. Is that correct?

*** No. The assessment seems to have been made without knowledge of the change in the nature of the employment, and accordingly based on the earnings of the previous year (1927-28). The correct gross liability on the above facts is £136.

LETTERS, NOTES, ETC.

INFECTION IN PUBLIC BATHS.

"M.R.C.S." writes: With reference to the article by Drs. Daggett and Cove-Smith on the dangers of infection in public baths (August 17th, p. 296) and their recommendation that "those persons with colds, septic nasal conditions, . . . should not be allowed in public baths without leave from an aural surgeon," I am wondering how this should apply in the case of people with gonococcal infections. I have recently had a most distressing case of a girl, aged 11 years, with a vulvo-vaginitis of undoubted gonococcal origin. The only source of contamination could be traced to a recent visit to the public baths. She used her own towel and costume, so I suppose she must have sat down on a seat while dressing or undressing.

SCOLIOSIS.

MR. PAUL BERNARD ROTH (London, W.) writes: In the review of Dr. Steindler's book (August 10th, p. 264) you say of scoliosis that "in its slighter unprogressive form it is of no clinical importance whatever and is easily dealt with." This statement astounds me; it is contrary to all my experience. When a slight case is met with for the first time no one can tell that it is not going to develop into a severe case, and it is of the utmost clinical importance to recognize this and start treatment at once. On the other hand, when a severe case is met with one knows that it began as a slight case, and if diagnosed in time could have been prevented from getting any worse.

*** Our reviewer writes: I said that the unprogressive form was easily dealt with: I did not say that it needed no treatment. I had also in my mind the hundreds of cases diagnosed as scoliosis in school inspections by specialists such as Schulthers, which are for the most part untreated and suffer no ill results. Hoffa gave 2,553 scoliotics out of 8,000 children recorded by various observers.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 38, 39, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *136*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

158. Non-tuberculous Conditions simulating Pulmonary Tuberculosis.

A. DUDAN (*Rev. Méd. de la Suisse Romande*, June 25th, 1929, p. 377) deprecates the number of patients erroneously labelled tuberculous. He insists that not only bacteriological, but *x*-ray examinations, should be made in every case to confirm a diagnosis arrived at in the course of routine examination. He considers also that the advice of an expert oto-rhino-laryngologist should be sought whenever there is any affection of the upper air passages; he cites instances of patients suffering from various affections of these passages who were wrongly diagnosed as tuberculous. In support of his contention he quotes Rist's statistical investigation of the sixth French army at Compiègne in 1916, in which it is shown that 192 men were diagnosed as tuberculous, but after thorough examination only 53 of these were proved to be the subjects of active, latent, or cured tuberculosis. Again, in 1918, of 342 patients so diagnosed in Paris no more than 37 had actually contracted the disease. Among 1,000 cases examined in 1919–20 at the Léon-Bourgeois anti-tuberculous dispensary at Paris only 330 were tuberculous. More recently the author examined 70 Swiss soldiers who were suspected of tuberculosis, and found that 23 showed evidence of active, latent, or cured disease, whereas 47 cases had an inflammatory condition of the respiratory passages, the majority of which were due to acute or chronic morbid conditions of the rhino-pharynx. Dudan concludes his article by remarking that not only is much misery—mental, economical, and social—caused by a false diagnosis of tuberculosis, but also that many patients who are suffering from a more benign affection are not cured because it passes unrecognized.

159. Statistics of Peptic Ulceration.

E. S. EMERY and R. T. MONROE (*Arch. Int. Med.*, June, 1929, p. 846) have studied 556 cases of peptic ulcer over a period of thirteen years, and summarized their findings. Of 407 patients who were admitted to medical wards, 155 were eventually transferred to the surgical side for operation; 149 other patients were admitted direct to the surgical wards. The duration of observation varied from six months to thirteen years, with an average of just over four years. The number of cases with ulcer entering the medical service was 1.85 per cent. of the total number of admissions, which agrees approximately with the experiences of other observers; the average age in years at which symptoms were first noticed was 35.9 for males and 37.8 for females. No connexion between the condition and occupations involving exertion was noted, and no definite hereditary tendency appeared to exist. Hyperacidity was present in 50 per cent. of the cases, and there was only one case of achlorhydria, which presented no symptoms, the diagnosis depending only on the *x*-ray findings, while in 36 cases (7 per cent.) the *x* rays showed no evidence of ulcer. Haemorrhage occurred in 194 (34.8 per cent.) of the cases, being fatal in 8, and after the first two years of symptoms the proportion fell to 23 per cent. After an average observation period of four years about 60 per cent. of the patients were found to be relieved by treatment, of which the strict Sippy method was the best medically, and gastro-enterostomy with plication of the pylorus the best surgically. While surgery seemed to be more effective, the results were worse than in those treated medically. The authors conclude that cure is rare, the present methods of treatment being only palliative; the advantages and disadvantages of the different methods must be carefully considered, the best results depending upon a wise choice for each individual case.

160. Nervous Complications of Influenza.

J. HALLÉ (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, May 20th, 1929, p. 618) records a familial epidemic of influenza in which the father and three of the five children showed well-marked nervous symptoms. The father's attack began with intense headache which persisted several days, and severe pain in the epigastrium which lasted three days and was not accompanied by diarrhoea, vomiting, or distension. This solar syndrome was accompanied by a horizontal nystagmus, which continued for a few days and then disappeared. There were no other cerebral or meningeal signs. The eldest daughter, aged 6, showed almost the same abdominal symptoms as her father, suggestive of peritonitis, which subsided in two days. The eldest boy, aged 15, had sialorrhoea which lasted for three days; and the youngest boy, aged 12, developed a transient psychosis during which he spoke incoherently and failed to recognize his parents. J. Comby described cases of convulsive influenza—that is, cases in which convulsions occurred at the onset or during the course of the disease, as well as transient and permanent psychoses giving rise to dementia and more or less extensive spastic paralysis.

161. Etiology of Rheumatic Fever and Tonsillitis.

J. T. CLARKE (*Brit. Journ. Child. Dis.*, April–June, 1929, p. 99) maintains that the geographical distribution of rheumatic fever and of *Ceratophyllus fasciatus*, the common rat-flea of northern temperate climates, is so similar as to make it seem possible that the insect is in some way connected with the etiology of the disease. The similarities are not only those of geographical and local distribution, but also of temperature and humidity, temperature being the most important. According to Clarke, rheumatic fever does not enter through those conditions of the throat which seem to be caused by overcrowding and bad ventilation, but there may be an association with the inflamed throats which are caused by the access of drain and sewer gas to houses. Defects in sanitation may admit not only drain gas into dwellings, but the rat with its flea as well, while the fact that the disease may occur without an inflamed throat suggests that it is the flea, and not the gas, which causes rheumatic fever.

162. Tracheo-bronchial Diphtheria.

N. T. WELFORD (*Amer. Journ. Dis. Child.*, May, 1929, p. 944), who records twenty-four cases in patients aged from 1 to 10 years, states that the malignant form of diphtheria which involves the trachea and bronchi has received rather scanty attention in medical literature. There are two types of cases: in one the membrane is formed in the smaller bronchi and extends upwards into the trachea, and in the other the membrane is formed above and spreads downwards into the bronchi. The most distinctive features of tracheo-bronchial diphtheria are severe toxaemia, marked intercostal and epigastric recession, in contrast with the recession of the suprasternal, supraclavicular, and infraclavicular spaces in laryngeal diphtheria, retention of voice, suppression of breath sounds, and hyper-resonance due to extensive emphysema or to distension of the lung with air which is unable to escape. Necropsies, which were performed in twenty-two of Welford's cases, showed that atelectasis caused by membranous obstruction was frequent. Treatment consists in the administration of large doses of antitoxin, and bronchoscopy with aspiration before the onset of myocardial failure.

Surgery.

163. The Small Deep Graft.

J. S. DAVIS (*Annals of Surgery*, June, 1929, p. 902) distinguishes between the small deep graft and Reverdin grafts, and advocates the use of the former, which include the full thickness of the skin at its centre; they should be round or irregularly oval in shape, and range between 0.4 and 0.5 cm. in diameter, tapering off toward the edges, where they are quite thin. Small deep grafts should preferably be taken from the upper anterior surface of the thigh, and may be placed on a fresh wound or on a granulating surface, which should be clean, firm, rose-pink in colour, and not exuberant. This surface is prepared the day preceding grafting by covering it, after cleansing, with a thick flat pad of gauze saturated with salt solution. Immediately before operation the wound is washed with ether and then salt solution. Before grafting the surface of the wound must be dry but not glazed. The grafts are cut under local anaesthesia, a piece of epidermis being picked up on an intestinal needle and raised so that a little cone is formed. This is cut through with a sharp scalpel, the grafts being cut in vertical rows running upwards across the area marked out, and transferred at once to the raw surface on the granulations. There should be a narrow rim of undisturbed epithelium left between the pits made by cutting the grafts. After two or three rows of grafts have been applied a strip of rubber protective about 2.5 cm. wide, in which V-shaped slits have been cut, is placed over the grafts and pressed downwards firmly. Silver foil dressing covered with a flat gauze dressing is the most satisfactory for the area from which the grafts

have been cut, and should be left undisturbed for about two weeks. Grafts which are on a granulating surface should have dressings changed after forty-eight hours; those on a fresh wound may be left for a week, but after the first dressing the grafted area should be dressed every day, at first with protective strips and then with bland ointment or 8 per cent. scarlet-red ointment to stimulate growth. Compresses of gauze saturated with salt solution may be used after the grafts have become firmly attached, and when the newly formed epithelium from the grafts and the wound edges has fused, stearate of zinc powder and exposure to the air are helpful. Three weeks after healing gentle massage should be started and be continued until the grafted area slides easily over the underlying tissues.

164. Results of Artificial Pneumothorax Treatment.

L. B. SMITH (*Tidsskr. f. d. Norske Laegefor.*, June 1st, 1929, p. 532) records the results achieved at the public sanatorium, Laudeskogen, in Norway, with artificial pneumothorax treatment between 1917 and 1926. During this ten-year period 3,035 patients were admitted, of whom 270 were considered to be suitable for this treatment. Fifteen patients already had an artificial pneumothorax when admitted; with the addition of these, the proportion of patients selected for this treatment was 9.2 per cent. of the total. Only in 3 of these 235 patients could no tubercle bacilli be found in the sputum. Cavities were found in 185 cases. In 141 cases extensive pleural adhesions prevented the induction of a pneumothorax, and in 10 other cases the pleural pocket was so small that the injections had to be discontinued. Among the patients in whom an adequate collapse of the lung was achieved there were 49 who were febrile at the beginning of the treatment; 35 of them became afebrile after the pneumothorax had been induced. Of the 134 patients in whom a pneumothorax was successfully induced, 105, or 78.4 per cent., were discharged fully or partly fit for work, whereas this was the case with only 88 of the 151 patients (58.3 per cent.) in whom pneumothorax could not be induced. The difference between these two classes was still greater when the fate of the patients was investigated in 1928, when every patient was traced. In 11 cases among those in which a pneumothorax had been successfully induced a thoracoplastic operation had subsequently been performed. Among the remaining 123 there were as many as 67, or 54.5 per cent., who were still fully or partly fit for work. On the other hand, among the 151 patients in whom a pneumothorax could not be induced there were 23 who subsequently underwent a thoracoplastic operation. After the subtraction of these cases there remained 128 patients, only 25 of whom (19.5 per cent.) were still fully or partly fit for work in 1928. In 72 of the 134 patients (53.7 per cent.) the pneumothorax was complicated by a pleural effusion, but only in two cases did an empyema develop; in 83.3 per cent. of the pleural effusions this complication ensued within six months of the induction of the pneumothorax.

165. Cysts of the Common Bile Duct.

L. DI NATALE (*Arch. Ital. di Chir.*, May, 1929, p. 553), who records an illustrative case in a man, aged 47, who died twenty-eight hours after operation, states that cysts of the common bile duct are very rare, only 70 having been recorded. They are most frequently met with in females, and between the ages of 15 and 20. The oldest patient was one aged 47, reported by Wagner, while Heiliger saw one in a foetus. Most authorities regard the cysts as due to a congenital teratological disturbance. The cystic process may affect the upper or middle part of the common bile duct and extend to the hepatic duct, or, in rare instances, to the cystic duct. The lower part of the bile duct does not take part in the process. The most frequent symptoms are intermittent jaundice, a palpable tumour in the right hypochondrium, closely connected with the liver and presenting signs of fluctuation, and pain which is usually colicky, less often continuous. The condition must be distinguished from empyema or hydrops of the gall-bladder, hydatid or simple cysts of the liver, and pancreatic or mesenteric cysts. The diagnosis has only once been made (by Nougebauer) before operation. Treatment, which is entirely surgical, consists in establishing an anastomosis between the cyst and the stomach.

166. Treatment of Varicose Ulcers.

H. H. TROUT (*Arch. of Surg.*, June, 1929, p. 2280) describes a method of treatment of ulcers due to varicose veins and lymphatic blockage which was successful in 25 cases out of 28; in the only unsuccessful one an epithelioma developed at the site of the skin grafts and the patient refused radium treatment. All the other patients were relieved from pain, the ulcers were completely healed, the swelling of the leg was greatly reduced, and the patients were enabled to return to their various occupations. In each instance the symptoms were more or less similar—swelling of the feet and legs below and around the ulcer, which exuded a thin, serous, odoriferous, pale yellow fluid. The ulcers usually started on the inner and lower side of the leg and spread until they became "saddle shaped," and sometimes encircled the leg. Trout remarks that the method of operation must vary according to the type of varicose vein, but in every case the saphenous vein must be tied off close to its entrance to the femoral vein before the veins in the leg are attacked. The operation advocated for extensive or multiple ulcers is the method used by Kondoleon in his treatment for elephantiasis, with wide excision of the ulcer and the employment of total thickness skin grafts when possible. The clinical results indicate a regeneration of the lymph channels or a rapid establishment of a collateral lymphatic circulation. Periarterial sympathectomy was tried in two cases, but did not result in the healing or sterilization of the ulcer.

Therapeutics.

167. The Therapeutics of Biliary Lithiasis.

C. DREYFUS (*Paris Méd.*, May 18th, 1929, p. 496) mentions that nowadays gall-stones are found more frequently by modern clinical methods, and that a certain number of troubles, hitherto of obscure origin, may be attributable to them. Only a small proportion of people with gall-stones suffer from them, and treatment is only required in these cases. In the acute attack of biliary colic the author advocates hypodermic injections of morphine combined with atropine, but mentions Laewen's method of injecting 10 c.cm. of novocain-adrenaline on the right side of the ninth and tenth dorsal vertebrae. After the pain has subsided a purgative should be given to prevent biliary and intestinal stasis; castor oil and sodium and magnesium sulphates, but not calomel, are recommended. Views regarding the diet treatment have in recent years undergone some modification, since it has been shown that hypercholesterinaemia is not followed by the deposition of cholesterin in the gall-badder. Fats cause fairly strong evacuation of the gall-bladder, and fats of low melting point, such as cream, butter, and olive oil, may be useful in moderate quantities. The beginning of many cases of cholelithiasis during the war has been attributed to a diet poor in fats. Diet should be especially directed to assure the regular functioning of the intestinal canal. Drug treatment must aim at avoiding further colic attacks and at preventing the formation of calculi. The idea of dissolving stones *in situ* is still of hypothetical interest, and it is probably impossible to disinfect effectively the biliary passages. The questions of medical drainage by cholagogues and Einhorn's tube are discussed. Magnesium sulphate and peptone are excellent cholagogues, and are said to be as efficacious when taken together by the mouth as when administered by the tube. To avoid undue optimism in treatment by medicine Kehr's aphorism is quoted, "Morphine and purgatives are the medicines to employ in the treatment of gall-stones; everything else can only do harm." The author adds that there is a tendency now to operate in an earlier stage of the disease, before permanent and extensive harm has been done to the liver and biliary apparatus. Mortality figures are smaller in the lower age groups. In nearly all gall-stone cases the wall of the gall-bladder is found to be infected, so cholecystectomy is cited as the operation of choice. Exploration of the bile ducts, and drainage when infected, must be performed. To avoid post-operative complications, the daily administration of insulin is advocated before operation.

168. Intravenous Injections of Adrenaline in Cardio-vascular Collapse.

H. E. PEARSE, jun. (*Journ. Amer. Med. Assoc.*, April 13th, 1929, p. 1263), reports two cases in which epinephrine—the standardized adrenaline product of the *U.S. Pharmacopoeia*—was injected with marked success in cases of cardio-vascular collapse. On one occasion an operation was being conducted for prostatic hypertrophy in a patient with arterio-sclerosis and hypertension, and in the other instance cystoscopy was in progress under caudal anaesthesia. In both cases the possibility of saving the patient's life appeared to be poor, and the recovery was so dramatic that the author concludes that this method of resuscitation is worthy of being borne in mind, even though it may be seldom required. The first patient had previously received three doses of epinephrine, each of 5 minims, subcutaneously, without any benefit, but a subsequent intravenous injection of 5 minims brought about an immediate rise in blood pressure, the patient quickly becoming conscious. In the second case also subcutaneous injections of epinephrine had proved ineffective, but 4 minims

given intravenously brought about a rapid and high increase in the blood pressure. The author considers that 5 minims is the maximum dose that should be given intravenously at any one time.

169. Treatment of Ophthalmia Neonatorum.

As a prophylaxis against gonorrhoeal ophthalmia in infants W. G. RICKER (*New England Journ. of Med.*, May 23rd, 1929, p. 1101) maintains that the proper cleansing of the region of the eyes at the right time is more essential even than the instillation of silver nitrate. At the moment of birth, and before the cord is tied, the child's head should be dried to avoid entrance of any of the fluids from the birth canal into the eyes. The face should then be carefully cleansed, especially the region of the eyes; it is well to sponge the eyelids and upper portion of the face with alcohol. Extreme care should be taken not to open the eyelids until the skin of both upper and lower lids is completely free of any maternal secretions. The lids may then be carefully separated, and any material adhering to the lashes should be carefully sponged away. As an additional precaution one or two drops of 1 per cent. silver nitrate solution may be instilled into each conjunctival sac. An important procedure, should ophthalmia develop, is to free the cornea of pus. The pus should be removed at frequent intervals, as often as every ten or fifteen minutes in aggravated cases. The lids should be opened, even if this should involve the cutting of the outer canthus, so as to allow the pus to escape. At the same time the eye or eyes should be freely irrigated with boric acid or normal saline solution. Ricker has treated several cases by this method alone without the use of any form of silver or any other medication, and in no case was there any loss of vision.

Anaesthetics.

170. Precautionary Methods in General Anaesthesia.

J. C. WADMORE (*New Zealand Med. Journ.*, April, 1929, p. 108) discusses the various steps that should be taken to render general anaesthesia a safe procedure, and emphasizes the value of frequent employment of the sphygmomanometer, since the pulse pressure constitutes the most helpful single indication of a safe operative risk. The tone of the heart muscle and vascular system must be estimated before an operation, and also the quality and volume of the patient's blood. In the first place, there should be no undue dyspnoea after moderate exertion; the effect of posture on the action of the heart affords a useful indication of its condition. Blomfield's test, in which patients are made to hold their breath for thirty seconds, is recommended, and the warning is given that myocardial degeneration and profound anaemia are equally dangerous, whether gas or an ordinary anaesthetic is used. Wadmore mentions the value of preliminary hypodermic injections of morphine and scopolamine in the case of alcoholics and very nervous patients with tachycardia. Morphine must, however, be avoided in low blood pressure cases; *in high blood pressure it should always be associated with scopolamine. He prefers the open ether method*, using eight layers of gauze, or chloroform or a chloroform-ether mixture on lint. A condensing towel is essential with open ether, but with mixtures it is risky in adults, and highly dangerous in the case of children. It should not be used at all with chloroform, except possibly by an experienced man to control a noisy alcoholic. Rigidity of the patient is often due to anoxaemia, which can be combated by inhalations of oxygen. Open ether continued during a long operation tends to lower the body temperature dangerously, and in high concentration has an irritant effect. In cranial surgery the anaesthetist must remember the danger of the cessation of respiration when the skull is trephined; this may also occur during a laminectomy. Wadmore comments on various other dangers, including the association of valvular disease of the heart with auricular fibrillation, cardio-sclerosis, and the hyperadrenalinaemia associated with the menopause, when chloroform is contraindicated. He concludes that a still closer co-operation between the surgeon and anaesthetist is desirable; that the choice of anaesthetic needs more exact consideration than is generally given; and that anaesthesia should cease to be an "adventure" for the patient or anaesthetist.

171. Paravertebral Anaesthesia in Urology.

As the result of 1,000 operations on the kidney and ureter, H. B. HERMANN and E. DÓZSA (*Surg., Gynecol. and Obstet.*, March, 1929, p. 375) advocate the use of paravertebral anaesthesia in urological operations. The disadvantages of inhalation, splanchnic, or spinal anaesthesia are not encountered; the method is said to be absolutely safe; the technique is uncomplicated and easily performed; and there are no contra-indications to its use, such as a high or low blood pressure, poor renal function, cardiac lesions, or pulmonary involvement. Three necessary factors for success with this method are: the co-operation of the patient, a good anaesthetic, and proper technique. As the confidence of the patient is of paramount importance, persons of low mentality and highly neurotic and apprehensive patients are not proper subjects for this method. The evening before operation the patient is given 8 grains of veronal to ensure sleep, and half an hour before the operation 1/3 grain of morphine is injected. Novocain is the anaesthetic of choice, and the solution may be prepared from tablets, each containing 0.125 gram of novocain and 0.000125 gram of adrenaline. The requisite strength of 1 per cent. of novocain is obtained by dissolving eight tablets in 100 c.cm. of physiological salt solution. This solution must be freshly prepared before each operation and sterilized by boiling. The adrenaline, by constricting the blood vessels, causes a slow absorption of the novocain, the effect of which is thus more intensive and lasting; the anaesthesia lasts for *two hours. In order to obtain a good anaesthesia in renal and ureteral operations*, the eighth to the twelfth dorsal nerves—that is, the last five intercostal and the first lumbar—should be blocked. If work on the lower part of the ureter is necessary, the second and third lumbar nerves should also be anaesthetized. The technique is fully described. In renal operations 150 c.cm. of the anaesthetic is used; when the ureter is laid free, or in patients with very thick abdominal walls, an additional 50 c.cm. is requisite. No toxic symptoms have been noted following the use of this large amount, and no untoward effects, such as post-operative haemorrhage, have resulted from the adrenaline. The injection of novocain into the pedicle and surrounding peritoneum, or light ether anaesthesia during the tying of the renal artery and vein, has not been found necessary. Slight transient symptoms, such as cardiac palpitation, dizziness, and vomiting, may occur in nervous patients. These have been ascribed to the cerebral effects of the novocain, but the pre-operative administration of morphine may be partly responsible for them.

172. Post-anaesthetic Acetonuria.

N. GARBER (*Zentralbl. f. Chir.*, May 18th, 1929, p. 1224) *has inquired into the presence of acetonuria in 300 cases* before and after surgical operation. He finds that it is attributable to a combination of injurious agents. Disturbance is caused by the operation itself, and especially by severe operations on the pancreas, rectum, gall-bladder, or in cases of disease associated with a general cachectic state. Acetonuria is favoured by inadequate dietetic preparation for the operation, and especially by chloroform narcosis. There is said to be also a constitutional predisposition to its occurrence in women, in asthenic patients, and those suffering from disease of the pancreas. Garber considers the condition to be a primary carbohydrate acidosis caused by the *direct action of the narcotic on the oxidizing processes of* metabolism; *a further action of the narcotic is a glycogen* impoverishment of the body which, if severe, induces a secondary acidosis by disturbing the combustion of fat. Acetonuria is a sign of hyperacidity of the body. In the author's series it was observed after operation in 59.5 per cent. of the cases. In 26 instances the condition was treated by injecting intracutaneously 300 to 700 grams of a 5 per cent. glucose solution, together with rectal injections of soda. With the disappearance of the acetone the general condition of the patient improves. If acetone is detected before the operation, glucose injections are given until the acetone has disappeared. After the operation the glucose treatment is started on the second or third day, and the clinical progress of the case is much favoured.

Obstetrics and Gynaecology.

173. Value of Mercurochrome in Caesarean Section.

H. W. MAYES (*Amer. Journ. Obstet. and Gynecol.*, May, 1929, p. 645) points out that the high morbidity and mortality following Caesarean section is not wholly due to the operation itself; puerperal infection accounts for nearly one-half of the deaths after this procedure. In a previous paper the author has shown the benefits from the use of a 4 per cent. solution of mercurochrome as a vaginal antiseptic during labour and delivery, and now compares the results in two series of cases of Caesarean section, in one of which the drug was thus employed. In 218 Caesarean sections with mercurochrome the morbidity was 42.2 per cent. and the mortality 3.2 per cent., with only one death from sepsis. In 120 cases without this drug the morbidity was 57.6 per cent. and the mortality 6.7 per cent., with four deaths from sepsis. In the mercurochrome series the parity of the mother had very little effect on morbidity, and the abdominal wound healed

by primary union in all but 8.2 per cent. Without mercurochrome the morbidity was 20.4 per cent. greater in primiparae, and 12.5 per cent. of the abdominal wounds were infected. Mayes believes that the use of mercurochrome as a vaginal antiseptic during labour adds greatly to the mother's safety in the event of Caesarean section becoming necessary; that the patient is not potentially infected, even though previous attempts at delivery have been made; and that low Caesarean section is of little or no advantage over the classic operation. The technique of this method, which includes careful preparation of the peri ieum and surrounding area, is described.

174. Lipiodol in the Diagnosis of Sterility.

R. IMBERT (*Paris Méd.*, May 25th, 1929, p. 515) draws attention to a recent article by Ledoux-Lebard and Claude Béclère in which they maintain that the tube is blocked if lip odol fails to pass into the peritoneal cavity when the cervix is efficiently plugged and a pressure of 30 cm. of mercury maintained for several minutes. They hold, further, that this fact has been proved not only by experiment, but by tests performed on the specimens subsequent to surgical removal. Imbert, who disagrees with this view, reports the case of a patient who complained of pain in the right iliac fossa, of long duration, and of such severity as to interfere with her daily work. Vaginal examination showed a slightly enlarged and pathological ovary on the right side. Lipiodol was injected into the uterus, after the manner of Cotte, using a pressure of 30 cm. of mercury; *x*-ray photographs, taken immediately and twenty-four hours later, showed quite definitely an obstruction at the infundibulum on the right side, the left tube being patent for the whole of its length. Moreover, there were no opaque seeds shown on the right side, although they were undoubtedly present on the left. A right tubal obstruction, situated at the infundibulum, was diagnosed, and the appendages on the right side were removed. Following the operation the author, to test the accuracy of the radiographic findings, injected water into the tubal lumen through the divided isthmic portion, and found that this water passed not only along the length of the tube, but through the fimbriated extremity, at a low pressure. He suggests that this apparent impermeability of the tube may have been due to a spasm or to the viscosity of the lipiodol.

175. Repeated Infections in Pregnancy.

H. MAGOS (*Bruxelles-Médical*, May 26th, 1929, p. 865) publishes an account of a state of grave infection occurring during two successive pregnancies in the same patient. The condition of the patient was such that on both occasions a differential diagnosis between the pre-eclamptic state and acute yellow atrophy of the liver was impossible. At the eighth month she had intense headache and oedema of the legs, with diminished urine. The dominating symptom was frequent vomiting of blood-stained bile and melaena. The blood pressure was high. On the first occasion albumin was present, but not on the second. Red blood cells were found in the urine each time. There was slight jaundice, but no fits and no coma. Spontaneous delivery of a live child occurred at eight and a half months in the first pregnancy; the infant was extremely thin and feeble, and had suffered from the effects of the toxaemia, but it lived. The second pregnancy was closely observed throughout, and the patient was carefully dieted, but at the eighth month exactly the same symptoms supervened, with the exception of albuminuria. Induction was considered necessary in the interests of the mother, and the infant was stillborn. Afebrile phlebitis followed both deliveries, but otherwise the patient's recovery was without incident, and she resumed her normal life.

Pathology.

176. The Effect of Anaphylaxis on the Course of Infection.

C. G. BULL and C. M. MCKEE (*Amer. Journ. of Hygiene*, May, 1929, p. 665) find that the intranasal inoculation of 0.1 c.cm. of an eighteen-hour blood-broth culture of a virulent pneumococcus strain produces in the rabbit a general infection attended by a marked rise in temperature and a positive blood culture. Such rabbits become hypersensitive to pneumococcal autolysates—prepared by allowing a heavy suspension of pneumococci from eighteen-hour blood-agar plates to autolyse in 0.5 per cent. phenolized saline for three or four days at incubator temperature. The intradermal inoculation of 0.2 c.cm. of autolysate gives rise to a local reaction, commencing four to six hours after inoculation, reaching its height in twenty-four to forty-eight hours, and showing signs of retrogression at seventy-two hours. The milder reactions are characterized by redness and oedema, but in the severer types necrosis occurs. The hypersensitiveness may also be demonstrated by the intravenous injection of autolysate. The injection of 0.3 to 0.6 c.cm. by this route results in acute anaphylactic shock, with death in a minute or two. Experiments showed that the hypersensitive state developed about forty-eight hours after the primary pneumococcal infection; it apparently reached its height shortly after recovery from the infection, and persisted for at least four months. It was found possible to produce hypersensitiveness by frequent intravenous inoculations of killed pneumococci, but the degree of hypersensitiveness attained by this method was apparently much inferior to that following actual infection. A very important observation was made on the relationship between local anaphylactic shock and the infection of the tissues with other organisms. It was found that if, after a rabbit had recovered from a pneumococcal infection, *Past. lepiseptica*—an organism that sometimes gives rise to sniffles, pneumonia, and septicaemia—was instilled into the nose, no sign of disease developed. But if, a few days later, 0.2 c.cm. of pneumococcal autolysate was injected intranasally so as to produce a local shock, the rabbits became ill and died in a few hours to a few days from *Past. lepiseptica* infection. It would appear that the occurrence of local shock interferes with the resistance of the tissues, and allows a latent infection to become active.

177. The Toxicity of Bile.

A CONDITION of intense shock follows the escape of bile into the peritoneum, and, though the clinical pictures of this condition and of obstructive jaundice are entirely unlike, bile is the underlying etiological factor in each. It would seem that in obstructive jaundice the bile in the blood stream may be detoxicated or, owing to depression of liver function, all the normal elements of the bile may not escape into the circulation. As the result of animal experiments, King and Stewart concluded that the toxicity of bile was due to the pigment. After its injection into dogs they observed a rise in the blood calcium, and believed that the calcium combined with the pigment, rendering it non-toxic, and that the delayed coagulation time in obstructive jaundice was due to the calcium being combined and leaving none available for the process of coagulation. Walters, and Lee and Vincent, have emphasized the importance of calcium administration to shorten the coagulation time in this disease. W. C. EMERSON (*Journ. Lab. and Clin. Med.*, May, 1929, p. 714) has made a number of experiments to determine whether calcium has a true protective effect against the toxicity of bile; if this were demonstrated, the intravenous administration of a soluble calcium salt would be indicated in all cases of suspected bile peritonitis. These experiments showed that calcium chloride has no such protective effect, and therefore would not be beneficial in fulminating bile peritonitis. They also suggest that in obstructive jaundice the calcium is not combined with the toxic element of the bile but with some other constituent, possibly the protein, and that its beneficial action is limited to its effect on the coagulation time of the blood.

178. An Agar-Method for the Isolation of Water Spirochaetes.

J. ADAMSKI (*Zentralbl. f. Bakt.*, June 28th, 1929, p. 476) has devised a method for the isolation of *Leptospira biflexa*, which he considers to be very much superior to the current practice involving the use of filter candles. The method depends essentially on the greater motility of spirochaetes in a viscous medium, as compared with that of bacteria and spirilla. Thus it is found that, in a medium containing about 1.2 to 1.5 per cent. agar, spirochaetes are able to penetrate into the depth of the medium, whereas bacteria remain confined to the surface. In practice the author prepares a medium of the following composition. A 1.2 to 1.5 per cent. watery suspension of agar is mixed with 0.25 per cent. of human faeces; the mixture is steamed, filtered, adjusted to a *p*H of 7 to 7.2, and sterilized by autoclaving for fifteen minutes at 120° C. The medium is poured into Petri dishes, in a layer 1 to 1.5 cm. high. When the surface is fairly dry, the plate is inoculated in the centre with tap-slime or other material containing the spirochaetes, and incubated at room temperature, bottom downwards, for eight to fifteen days. Examination of the agar taken from beneath the surface reveals the presence of spirochaetes, which can then be transferred to a suitable medium, such as Noguchi's serum agar. If the water used for inoculating contains very few spirochaetes, it is desirable to practise preliminary enrichment by Hindle's method. By this means the author has been able to cultivate leptospirae from practically every specimen of water examined. The method is said to be of value likewise in the isolation of *Trep. buccalis* and other mouth spirochaetes.

FELAMINE

BRAND

SANDOZ

Felamine, an association of the most powerful cholagogue — pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, provides a rational and effective treatment of biliary lithiasis, cholangitis, hepatitis, icterus, and all the symptoms of biliary insufficiency.

Felamine contains no accessory drugs. The cholagogic active principle (cholic acid) is present in an absolutely pure state, free from useless and harmful bile substances.

Indications.

Cholangitis, Cholecystitis, Hepatic Insufficiency, Hepatic Congestion, Jaundice, Chronic Constipation.

Felamine is supplied in Bottles of 50 and 250 Tablets at **5/-** *and* **20/-**

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the appaiatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, an[illegible] to the Hospital from the farm, gardens, and orchards of Moulton [illegible] is a feature of this branch, and patients are given every facility [illegible] in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56. Northampton), who can be seen in London by appointment.

NEURASTHENIA.
BELVOIR NURSING HOME, ASTON-ON-TRENT, DERBY.

Private Nursing Home for Neurasthenia and allied Functional Nervous Disorders, for general Convalescent Cases, and those requiring Electrical Treatment.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, Ultra-violet Light, and Massage is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week. For further particulars apply to—
Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.
Dr. Douglas-Morris can be seen by appointment in London.

HAYDOCK LODGE
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

MAUDSLEY HOSPITAL,
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE [illegible] Voluntary patients only.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.
IN-PATIENTS: (*a*) 160 beds (both sexes) in wards or separate rooms. (*b*) 13 private rooms (for ladies) with special sitting rooms, garden, and dietary.

Terms:

(*a*) **£5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.**
(*b*) **£6 6s. a week.**

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., M.R.C.P., F.R.C.S., Medical Superintendent.

CHISWICK HOUSE.

A Private Mental Hospital for the Treatment and Care of Mental and Nervous Disorders.

Now removed to:

CHISWICK HOUSE,
PINNER,
MIDDLESEX.

Telephone: PINNER 234.

A modern country house, 12 miles from Marble Arch, in beautiful secluded grounds.

Fees are from 10 guineas a week.

Voluntary Patients received for treatment.

DOUGLAS MACAULAY, M.D., D.P.M.

WONFORD HOUSE HOSPITAL,
EXETER, DEVON.

Telegrams: Exeter 2642. *Telephone*: Exeter 2642.

A registered Hospital for the treatment of patients of both sexes suffering from Nervous and Mental Disorders, situated in beautiful country within a mile and a half of the City of Exeter.

Hard and grass Tennis Courts, Croquet Lawn, Cricket Field, and all indoor amusements, Dancing, Concerts, Wireless, Billiards, Badminton. Occupational treatment.

The patients are carefully graded, and accommodation provides for the separate treatment of early recoverable and convalescent patients.

Voluntary and certified patients are received for treatment.

A prospectus and full particulars can be obtained from the Medical Superintendent.

BARNWOOD HOUSE,
GLOUCESTER.

A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L. M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital.

For particulars as to terms, etc., apply to—
ARTHUR TOWNSEND, M.D., Resident Supt
Telephone: No. 7 Barnwood.

UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE

(Associated with the General, Queen's, and Special Hospitals for Clinical Teaching.)

THE SESSION OPENS ON MONDAY, SEPTEMBER 30th, 1929.

The University grants Degrees in Medicine, Surgery, and Public Health, and a Diploma in Public Health; also Degrees and a Diploma in Dental Surgery.

The courses of instruction are also adapted to meet the requirements of other Universities and Licensing Bodies.

HOSPITAL APPOINTMENTS.

A large number of Resident Hospital appointments in Birmingham and District are open to qualified students of the School.

SCHOLARSHIPS, EXHIBITIONS, AND PRIZES.

Entrance and other Scholarships and Exhibitions and various Prizes and Medals are awarded annually in the Faculty of Medicine.

SCHOOL OF DENTISTRY. (University of Birmingham and Birmingham Dental Hospital.)

The School of Dentistry, in conjunction with the General and Queen's Hospitals, affords a complete curriculum for the Dental Diplomas and Dental Degrees of the University and all other Licensing Bodies. There is a Dental Scholarship of the value of £46 17s. 6d. offered annually.

PRE-MEDICAL AND PRE-DENTAL EXAMINATIONS.

The necessary Courses of Instruction in Chemistry and Physics and in Biology may be attended in the University.

RESIDENCE FOR UNDERGRADUATES AND OTHER STUDENTS.

There are Halls of Residence for Men and for Women Students. A register of approved lodgings is also kept by the Secretary of the University.

For Syllabus and further information apply to Prof. J. C. BRASH, M.A., M.D., Dean.

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL.

THE WINTER SESSION will Open on Tuesday, October 1st.

The Hospital is the largest in England. There are 839 beds in constant use. Last year: number of in-patients 14,698; new out-patients, 96,928; attendances, 555,762; new dental patients, 5,857; major operations, 7,649.

The MEDICAL COLLEGE and DENTAL SCHOOL are essentially modern, with large laboratories equipped with the latest and the most approved appliances. The STAFF is so large as to permit of individual attention being paid to all Students.

MEDICAL UNIT.—A Clinical Unit in Medicine, under the charge of a whole-time Director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research.

RESEARCH FUNDS to the value of over £113,000 permit of financial assistance being given to Students and Graduates engaged in Medical Research.

SCHOLARSHIPS and PRIZES to the value of £1,158 are awarded annually, including four Open Entrance Scholarships to the value of £350, and two Entrance Scholarships open to students of the Universities of Oxford and Cambridge to the value of £200.

APPOINTMENTS.—Over 160 Appointments are made annually from Students of the College recently qualified.

SPECIAL COURSES are held for all the University Examinations, for the Primary and Final Fellowship Examinations of the Royal College of Surgeons, and for the Membership Examination of the Royal College of Physicians.

HOSPITAL PRACTICE.—Exceptional opportunities are offered to qualified Practitioners wishing to attend the General Practice or the Practice of a Special Department of the Hospital.

A Clubs' Union, an Athletic Ground of over 13 acres, and a *Students' Hostel*, promote the recreation, health, and comfort of the Students.

For Prospectus and Particulars apply to the Dean (Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S.), who will be pleased to make arrangements for anyone wishing to see the Medical College and Dental School.

Full Schedule of Terms and Conditions will be forwarded on application.

Valentine's Meat-Juice

In **Typhoid Fever, Diarrhoea and Cholera Infantum,** when it is **Essential** to **Sustain** the patient **without irritating** the **Digestive Organs,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Richmond, Virginia, U. S. A.

ELIXIR FORMASAL Co
AND
TAB. ARTHRITONE

The combined treatment is giving excellent results in cases of Rheumatoid Arthritis which have stubbornly resisted all other forms of medication.
The results that are being obtained by the profession are very striking, and no practitioner can afford to be without a supply.

Please note, our preparations are not advertised to the public.

Price

ELIXIR FORMASAL Co. 4/3 lb, WINCHESTER 4/- lb.
TAB. ARTHRITONE 4/6 Per 100 — 32/6 Per 1,000.

HOUGH - HOSEASON & Co LTD MANCHESTER
PHARMACEUTICAL SPECIALISTS TO THE MEDICAL PROFESSION.

The Medical Profession
when prescribing
"Liquor Carbonis Detergens"
SHOULD ADD THE WORD
Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the *complete extraction of all the soluble antiseptic constitutents, is* attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

SCHACHT'S
Original Preparations
FOR THE USE OF
THE MEDICAL PROFESSION.

LIQ. BISMUTHI "SCHACHT."

Absolutely pure and perfectly stable. The original preparation and the most physiologically active solution of Bismuth. Dose: One drachm, diluted.

PEPSINA LIQUIDA "SCHACHT."

A palatable, standardized solution of gastric juice from the pig. Useful in the treatment of dyspepsia. In ten-minim doses it gives excellent results in infantile diarrhœa. Adult dose: One drachm, diluted.

PEPSINA LIQUIDA C. BISMUTHO "SCHACHT."

Each fluid drachm contains in a concentrated form, besides the Pepsina Liquida, one fluid drachm of Liquor Bismuthi "Schacht." Dose: One drachm, diluted.

PEPSINA LIQUIDA C. BISMUTHO CO. "SCHACHT."

Contains one grain of Soluble Euonymin in each fluid drachm, in addition to the Pepsine and Bismuth. Dose: One drachm, diluted.

BISEDIA.

A combination of Schacht's Liquor Bismuthi and Pepsina Liquida, with Morphia and Hydrocyanic Acid. Of the greatest value in the treatment of Acute Dyspepsia, Gastric Ulceration, Vomiting of Pregnancy, etc. Dose: Half to one drachm, diluted.

LIQ. CASCARÆ DULCIS "SCHACHT."

A palatable and very concentrated aromatic preparation of the finest Cascara Sagrada; free from bitterness and griping action. Dose: Quarter to one drachm.

LENIVA.

An excellent fruit laxative syrup, containing Alexandrian Senna, Figs, Prunes, Tamarinds, etc. Eminently suitable for delicate women and children. Dose: Half to two drachms, according to age.

ISSUED WEEKLY] [COPYRIGHT] [REGISTERED AS A NEWSPAPER

INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Made possible by an endowment fund, an Intermediate Hospital of 30 beds (which is being increased to 50 beds) is now open for suitable general surgical cases at 17, Park Lane, London, W.1, in which fees for a room cost now only two guineas a week, interest in the scheme having enabled a further reduction to be made since it was started.

(The whole scheme is an attempt to help people unable to pay ordinary full surgical expenses, and yet, at the same time, to avoid any semblance of a charity, which would be distasteful to such.)

All further particulars can be obtained from the Secretary or Matron at 17, Park Lane.
Telephones: Grosvenor 2312 & 2313.

A TYPICAL SCALE OF REDUCED FEES FOR SURGICAL CASES IN THE ANNEXE CLINIC OF THE HAROLD FINK MEMORIAL HOSPITAL AT 17, PARK LANE.

Hospital Fees, including Nursing, 2 guineas a week (limited to an average stay of 3 weeks)	£6 6 0
Dressings, Theatre Fees, etc.	1 1 0
Assistant Surgeon at operation	4 4 0
Anæsthetic Fee	4 4 0
Surgical Fees for Major Operation (nominal only, and from one-fifth usual charges, according to patient's means (say)	21 0 0
(From Thirty-five guineas inclusive fee)	£36 15 0

N.B.—The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant, who will take charge of the after-treatment while in hospital, and be paid direct by the patient his usual fees for such attendance, in addition to the fee as Anæsthetist or Assistant at operation.

When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon-in-Chief (with a view, for example, to a Bismuth Meal, Cystoscopic or X-ray Examination, etc.), all that is necessary is to telephone either the Secretary or Matron, and an appointment will be made. (Proportionately reduced nominal fees only charged therefor.)
Telephones: Grosvenor 2312 & 2313.

All rooms are of course separate, and hold one patient only, there being no wards.

By W. H. C. ROMANIS, F.R.C.S., and P. H. MITCHINER, F.R.C.S., Surgeons, St. Thomas's Hospital. Second Edition. Two Volumes. 674 Illustrations. 28s. Postage 1s. 3d.

THE QUEEN CHARLOTTE'S OBSTETRICS
By J. BRIGHT BANISTER, A. W. BOURNE, T. B. DAVIES, C. S. LANE-ROBERTS, L. G. PHILLIPS, L. C. RIVETT, Members of the Staff of the Hospital. 4 Col. Plates, 270 Figs. 18s. Post. 9d.

LAWRENCE'S DIABETIC LIFE
Its Control by Diet and Insulin. A Guide for Practitioners and Patients. By R. D. LAWRENCE, M.A., M.D. Fourth Edition. 12 Illustrations. 8s. 6d. Postage 4d.

YORKE & MAPLESTONE'S NEMATODE PARASITES OF VERTEBRATES
By WARRINGTON YORKE, M.D., Professor of Parasitology, University of Liverpool, and P. A. MAPLESTONE, D.S.O., M.B. With 307 Illustrations. 36s. Postage 9d.

LITTLEJOHN'S FORENSIC MEDICINE
Illustrated by Photographs and Descriptive Cases. By HARVEY LITTLEJOHN, M.B., F.R.C.S.Ed. 183 Illus. 15s. Postage 9d.

JELLETT'S PRACTICE OF GYNÆCOLOGY
By HENRY JELLETT, M.D., F.R.C.P.I., Ex-Master, Rotunda Hospital, Dublin. Fifth Edition. 417 Illustrations. 15 Coloured Plates. 25s. Postage 9d.

STARLING'S PRINCIPLES OF HUMAN PHYSIOLOGY
Fourth Edition. 570 Illustrations, 10 in Colour. 25s. Post. 1s.

THRESH & BEALE'S WATERS AND WATER SUPPLIES
By J. C. THRESH, D.Sc., M.D., and J. F. BEALE, M.R.C.S., D.P.H. Third Edition. 59 Illustrations. 25s. Postage 9d.

GWATHMEY'S ANÆSTHESIA
By JAMES T. GWATHMEY, President Am. Assoc. of Anæsthetists. Second Edition. 273 Illustrations. 25s. Postage 9d.

HEWLETT'S MANUAL OF BACTERIOLOGY
Eighth Edition. 38 Plates, 63 Text-figures. 18s. Post. 9d.

CRAIG'S PSYCHOLOGICAL MEDICINE
Fourth Edition, with the Collaboration of T. BEATON, O.B.E., M.D., Lecturer in Mental Diseases, Bethlem Royal Hospital. 25 Plates. 21s. Postage 9d.

The Recent Advances Series

12s. 6d. each, except Children and Surgery, 15s. each.

PULMONARY TUBERCULOSIS
L. S. T. BURRELL, M.D. 32 Plates and 17 Text-figures.

PSYCHIATRY
H. DEVINE, O.B.E., M.D. Illustrated.

BACTERIOLOGY
J. HENRY DIBLE, M.B., Ch.B. 24 Illustrations.

MEDICINE
G. E. BEAUMONT, D.M., F.R.C.P., and E. C. DODDS, M.D., M.R.C.P. Fourth Edition. 48 Illustrations.

OPHTHALMOLOGY
W. STEWART DUKE-ELDER, D.Sc., M.D., F.R.C.S. Second Edition. 4 Coloured Plates and 110 Text-figures.

DISEASES OF CHILDREN
W. J. PEARSON, D.S.O., D.M., F.R.C.P., and W. G. WYLLIE, M.D., M.R.C.P. 18 Plates and 32 Text-figures.

BIOCHEMISTRY
JOHN PRYDE, B.Sc., M.Sc. Second Edition. 38 Illustrations.

PREVENTIVE MEDICINE
J. F. C. HASLAM, M.D. *Ready in October.*

HÆMATOLOGY
A. PINEY, M.D. Second Edition. 4 Coloured Plates and 18 Text-figures.

CARDIOLOGY
TERENCE EAST, M.D., F.R.C.P., and C. W. C. BAIN, M.C., M.B.

NEUROLOGY
W. RUSSELL BRAIN, M.D., and E. B. STRAUSS, B.M., B.Ch. 37 Illustrations.

SURGERY
W. HENEAGE OGILVIE, M.D., F.R.C.S. Second Ed. 115 Illus.

ANATOMY
H. WOOLLARD, M.D. 4 Coloured Plates. 73 Text figures.

TROPICAL MEDICINE
SIR LEONARD ROGERS, M.D., F.R.S. Second Edition. 16 Illus.

OBSTETRICS AND GYNÆCOLOGY
ALECK W. BOURNE, M.B., B.Ch., F.R.C.S. Second Ed. 67 Illus.

PHYSIOLOGY
C. LOVATT EVANS, D.Sc., F.R.S. Third Edition. 86 Illus.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Sq., W.1

J. & A. CHURCHILL

Latest Books for Students and Practitioners

BOUSFIELD'S PRACTICAL GUIDE TO THE SCHICK TEST AND DIPHTHERIA AND SCARLET FEVER IMMUNIZATION

By GUY BOUSFIELD, M.B., B.S., Medical Officer, Diphtheria Immunization Clinics of Camberwell and Lambeth. 6 Illus. 5s. Postage 4d.

BERTWISTLE'S SURGICAL RADIOLOGY

By A. P. BERTWISTLE, M.B., Ch.B., F.R.C.S.Ed. With Introduction by D. P. D. WILKIE, O.B.E., F.R.C.S., Professor of Surgery, University of Edinburgh. 24 Illustrations. 8s. 6d. Postage 6d.

BURNS' INTRODUCTION TO BIOPHYSICS

By DAVID BURNS, D.Sc., Prof. Physiol., Univ. Durham. Second Edition. 116 Illustrations. 25s. Postage 9d.

JOHNSTON'S SYNOPSIS OF REGIONAL ANATOMY

By T. B. JOHNSTON, Prof. Anat., Univ. Lond. Second Edition. 11 Illustrations. 12s. 6d. Postage 6d.

DUKE-ELDER'S PRACTICE OF REFRACTION

By W. S. DUKE-ELDER, M.D., F.R.C.S., Assistant Ophthalmic Surgeon, St. George's Hospital. 208 Illus. 12s. 6d. Postage 6d.

PINEY'S DISEASES OF THE BLOOD

By A. PINEY, M.D., Ch.B., M.R.C.P., Research Pathologist, Cancer Hospital, London. 20 Illustrations, 6 in Colour. 12s. 6d. Postage 6d.

EDEN & HOLLAND'S MANUAL OF MIDWIFERY

By T. W. EDEN, M.D., F.R.C.S., and EARDLEY HOLLAND, M.D., F.R.C.S. Sixth Edition. 7 Plates and 393 Text-figures. 21s. Postage 9d.

SYDNEY SMITH'S FORENSIC MEDICINE

By SYDNEY SMITH, M.D., D.P.H., Regius Professor of Forensic Medicine, University of Edinburgh. Second Edition. 166 Illus. 24s. Postage 9d.

GOODHART & STILL'S DISEASES OF CHILDREN

By the late Sir J. F. GOODHART. Twelfth Edition, edited by G. F. STILL, M.D., F.R.C.P., Professor of Diseases of Children, King's College. 68 Illustrations. 28s. Postage 9d.

MOORE'S MEDICAL OPHTHALMOLOGY

By R. FOSTER MOORE, O.B.E., F.R.C.S., Ophthalmic Surgeon, St. Bartholomew's Hospital. Second Edition. 8 Plates and 92 other Illustrations. 18s. Postage 9d.

CAMERON'S TEXTBOOK OF BIOCHEMISTRY

For Students of Medicine and Science. By A. T. CAMERON, D.Sc., F.I.C., F.R.C.S., Professor of Biochemistry, University of Manitoba. 2 Plates and 12 Illustrations. 15s. Postage 6d.

GILTNER'S ELEMENTARY GENERAL MICROBIOLOGY

By WARD GILTNER, Professor of Bacteriology, Michigan State College. 99 Illustrations. 15s. Postage 9d.

PARSONS' DISEASES OF THE EYE

By Sir JOHN H. PARSONS, C.B.E., D.Sc., F.R.C.S., F.R.S. Fifth Edition. 21 Plates. 343 Illustrations. 19s. Postage 9d.

WILLIAMS' MINOR SURGERY AND BANDAGING

By GWYNNE WILLIAMS, M.S., F.R.C.S., Surgeon, University College Hospital. Nineteenth Edition. 247 Illustrations. 10s. 6d. Postage 5d.

JELLETT'S SHORT PRACTICE OF MIDWIFERY

By HENRY JELLETT, M.D. Ninth Edition. 263 Illustrations. 4 Colour Plates. 18s. Postage 9d.

HALE-WHITE'S MATERIA MEDICA, PHARMACY, PHARMACOLOGY AND THERAPEUTICS

By Sir W. HALE-WHITE, K.B.E., M.D., F.R.C.P. Nineteenth Edition. 10s. 6d. Postage 5d.

HERTSLET'S THE SKIN AND ITS USES

By DR. LEWIS HERTSLET. With Foreword by PROF. L. HILL, F.R.S., and DR. R. P. MACKENZIE. 10s. 6d. Postage 6d.

WINSBURY WHITE'S STONE IN THE URINARY TRACT

By H. P. WINSBURY WHITE, M.B., Ch.B., F.R.C.S., Hon. Assistant Surgeon, St. Paul's Hospital for Genito-Urinary Diseases. 2 Coloured Plates and 181 Text-figs. 25s. Post. 9d.

GOLDZIEHER'S THE ADRENALS—THEIR PHYSIOLOGY, PATHOLOGY AND DISEASES

By MAX A. GOLDZIEHER, M.D., Former Professor of Pathology, University of Budapest. 73 Illustrations. 30s. Postage 9d.

FALTA'S ENDOCRINE DISEASES

Translated and Edited by MILTON K. MEYERS, M.D. Foreword by Sir ARCHIBALD E. GARROD, K.C.M.G., M.D.(Oxon). 104 Illustrations. 36s. Postage 1s.

GOULDEN'S REFRACTION OF THE EYE

Including Physiological Optics. By CHARLES GOULDEN, O.B.E., M.D., F.R.C.S., Ophthalmic Surgeon, London Hospital. 180 Illustrations. 10s. 6d. Postage 6d.

ROWLANDS' & TURNER'S OPERATIONS OF SURGERY

By R. P. ROWLANDS, O.B.E., M.S.Lond., F.R.C.S.Eng., Surgeon to Guy's Hospital, and PHILIP TURNER, B.Sc., M.S.Lond., F.R.C.S.Eng., Surgeon to Guy's Hospital. Seventh Edition. 900 Illus., 43 in Colour. Two Volumes. 70s. Postage 1s. 3d.

NEAME & WILLIAMSON-NOBLE'S HANDBOOK OF OPHTHALMOLOGY

By HUMPHREY NEAME, F.R.C.S., Ophthal. Surg., Univ. Coll. Hosp., Lond., and F. A. WILLIAMSON-NOBLE, M.B., F.R.C.S., Assist. Ophthal. Surgeon, St. Mary's Hospital, London. 12 Plates and 194 Figures. 12s. 6d. Postage 9d.

JOHNSTON & SIMPSON'S PRINCIPLES OF PRACTICAL BACTERIOLOGY

By J. H. JOHNSTON, M.Sc., Lecturer in Pract. Chem., St. Bartholomew's Hosp. Med. Sch., and R. H. SIMPSON, M.D., M.R.C.P., Asst. Phys., East London Hosp. 5s. Postage 3d.

PANTON & MARRACK'S CLINICAL PATHOLOGY

By P. N. PANTON, M.A., M.B., B.C., Clin. Path., Lond. Hosp., and J. R. MARRACK, D.S.O., M.C., M.B., Chem. Path., Lond. Hosp. 12 Plates, 10 in Colour, and 51 Figures. 15s. Postage 9d.

MATTHES' DIFFERENTIAL DIAGNOSIS OF INTERNAL MEDICINE

By M. MATTHES, M.D. Translated with Extensive Additions by I. W. HELD, M.D., and M. H. GROSS, M.D. 176 Illustrations. 42s. Postage 1s.

EDEN & LOCKYER'S GYNÆCOLOGY

By T. W. EDEN, M.D., Consulting Physician, Queen Charlotte's Maternity Hospital, and CUTHBERT LOCKYER, M.D., Consulting Physician, Charing Cross and Royal Northern Hospitals. Third Edition. 32 Coloured Plates and 556 Illus. 35s. Post. 1s.

TAYLOR & POULTON'S PRACTICE OF MEDICINE

Thirteenth Edition. 48 Plates, 8 Coloured, and 93 Text-figures. 28s. Postage 1s.

DARLING'S SURGICAL NURSING AND AFTER-TREATMENT

Third Edition. 149 Illustrations. 8s. 6d. Postage 6d.

DARLING'S ELEMENTARY HYGIENE FOR NURSES

Fourth Edition. 54 Illustrations. 5s. Postage 4d.

LUCAS'S BOOK OF PRESCRIPTIONS

With an Index of Diseases and Remedies. Eleventh Edition. 10s. 6d. Postage 4d.

CLARK'S APPLIED PHARMACOLOGY

By A. J. CLARK, M.C., M.D., F.R.C.P., Professor of Materia Medica and Pharmacology, University of Edinburgh. Third Edition. 65 Illustrations. 15s. Postage 9d.

JAMESON & MARCHANT'S SYNOPSIS OF HYGIENE

By W. WILSON JAMESON, M.D., D.P.H., Medical Officer of Health, Hornsey, and F. T. MARCHANT, M.R.San.I. Second Edition. 21 Illustrations. 18s. Postage 9d.

EAST'S FORENSIC PSYCHIATRY IN CRIMINAL COURTS

By W. N. EAST, M.D., Medical Inspector, H.M. Prisons, England and Wales. 16s. Postage 6d.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Sq., W.1

Leading Text-Books

Cecil's Text-Book of Medicine

"The plan of presenting a text-book in which a large number of authorities have collaborated has obvious advantages to the student preparing for his final examination, and to the practitioner of more mature years seeking recent and reliable information. Dr. Cecil is to be congratulated on the success with which he has brought this magnum opus into being."—BRITISH MEDICAL JOUR.

By 130 Authors. Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical School. Octavo of 1,5'0 pages, illustrated. Cloth, 40s. net.

MacCallum's Text-Book of Pathology

"No doubt this book has often been taken down from the laboratory shelf to verify some small point, not to be replaced immediately the information sought has been obtained; it is apt to beguile the reader, enticing him to some stimulating thought. It teaches ideas rather than facts."—BRITISH MEDICAL JOURNAL.

By W. G. MACCALLUM, M.D., Professor of Pathology and Bacteriology, Johns Hopkins University. Octavo of 1,177 pages, 606 original illustrations, 50 in colours. New (4th) Edition. Cloth, 45s. net.

Howell's Text-Book of Physiology

"It is an encouraging sign of the times that a text-book so remote from any approach to the cram-book should have gained so much popularity with the medical student. . . . The author has succeeded in making his subject-matter interesting and in many parts fascinating—an art deplorably rare in physiological writings. The book inspires respect rather than criticism."
—EDINBURGH MEDICAL JOURNAL.

By WILLIAM H. HOWELL, M.D., Ph.D., Professor of Physiology, Johns Hopkins University, Baltimore. Tenth Edition. Octavo of 1,081 pages, illustrated. Cloth, 30s. net.

McGuigan's Text-Book of Therapeutics

"Professor McGuigan has succeeded in producing something quite different from the usual run of books on pharmacology and therapeutics suitable for undergraduates. . . . One can unhesitatingly recommend the book to the attention of students of medicine in search of an accurate book of reasonable dimensions."
SOUTH AFRICAN MEDICAL JOURNAL.

By HUGH ALISTER MCGUIGAN, Ph.D., M.D., Professor of Pharmacology and Therapeutics, University of I linois College of Medicine. Octavo of 660 pages, illustrated. Cloth, 28s. net.

Babcock's Text-Book of Surgery

"Takes a distinguished place among the many general text-books that are available. It is designed both for the student and the practitioner, as the author believes that, with the increase of clinical teaching and the declining importance of systematic lectures, the student must turn more to his reading for his theoretic background."—BRITISH MEDICAL JOURNAL.

By W. WAYNE BABCOCK, M.D., Professor of Surgery, Temple University, Philadelphia. Octavo of 1,367 pages, with 1,050 illustrations, 9 in colours. Cloth, 45s. net.

Boyd's Surgical Pathology

"Accurate, clear, and well illustrated. . . . An unusual but commendable feature for a book on pathology is the summary of symptoms which accompanies many descriptions, thus providing a link between the laboratory and the clinical sides. . . . The book is well described by Dr. W. J. Mayo as 'a sincere attempt to place pathology before the student and practitioner from the practical standpoint.'"—BRITISH MEDICAL JOURNAL.

By WILLIAM BOYD, M.D., M.R.C.P.Ed., F.R.S.Can., Professor of Pathology, [illegible] of 933 pages, with 476 plates. New (2nd) Ed [illegible]

Arey's Developmental Anatomy

"Professor Arey has published a text-book which includes more post-natal development than most other manuals of embryology. The outline presented of the more important developmental changes manifested after birth is a very valuable addition. . . . Professor Arey is to be congratulated on the production of a text-book of embryology which may be highly recommended and is likely to be used very widely."—BRITISH MEDICAL JOURNAL.

By LESLIE BRAINERD AREY, Professor of Anatomy at the Northwestern University Medical School, Chicago. Octavo of 433 pages, with 419 illustrations, many in colours. Cloth, 27s. 6d. net.

Sollmann's Manual of Pharmacology

"Of particular value to advanced students because a full account is given of the chief recent research work in the subjects dealt with, and moreover an excellent selected bibliography of a hundred pages is included. . . . The most extensive work of reference in pharmacology in our language."
—BRITISH MEDICAL JOURNAL.

By TORALD SOLLMANN, M.D., Professor of Pharmacology in the School of Medicine of Western Reserve University, Cleveland. Octavo of 1,184 pages, illustrated Third Edition. Cloth, 35s. net.

OXFORD MEDICAL PUBLICATIONS

A SHORT SELECTION FROM OUR LIST OF BOOKS FOR MEDICAL STUDENTS.

(COMPLETE LIST SENT ON REQUEST.)

A MANUAL OF PHYSICS
By J. A. CROWTHER, Sc.D. 2nd Edition. Pp. 553. 293 Figs. 14/- net.
Also in Sections:—I. Mechanics and Properties of Matter, 3/6 net; II. Heat, 3/- net; III. Light and Sound; 3/6 net; IV. Magnetism and Electricity, 4/- net; Answers to Numerical Examples, 1/- net.

PRACTICAL PHYSICS By the same author. Pp. 284. 94 Illustrations. 7/6 net.

QUALITATIVE & VOLUMETRIC ANALYSIS FOR MEDICAL STUDENTS
By H. LAMBOURNE, M.A., M.Sc., F.I.C., and J. A. MITCHELL, M.Sc. Pp. 66. 5/- net.

OUTLINES OF ZOOLOGY 8th Edition.
By Professor J. ARTHUR THOMSON. Pp. 1016. 528 Illustrations. Ready October.

MANUAL OF ELEMENTARY ZOOLOGY
By L. A. BORRADAILE, Sc.D. 6th Edition. Pp. 752. 25 Plates. 472 Illustrations. 16/- net.

ELEMENTARY ZOOLOGY FOR MEDICAL STUDENTS
By the same author. Pp. 386. 243 Illustrations. 6 Plates. 10/6 net.

HISTOLOGICAL TECHNIQUE
By H. M. CARLETON, M.A., B.Sc., D.Ph. Pp. 400. 17 Illustrations. 13/- net.

CUNNINGHAM'S TEXTBOOK OF ANATOMY
5th Edition. Pp 1606. 1109 Engravings, 613 in Colour, 2 Skiagraphs. 42/- net.

CUNNINGHAM'S MANUALS OF PRACTICAL ANATOMY. 3 Vols.
Vol. I. Superior and Inferior Extremities. Vol. II. Thorax and Abdomen.
Vol. III. Head and Neck. 8th Edition. each 12/6 net.

COMPANION TO MANUALS OF PRACTICAL ANATOMY
By E. B. JAMIESON, M.D. 2nd Edition. Pp. 553. 8/6 net.

POCKET ATLAS OF ANATOMY
By VICTOR PAUCHET and S. DUPRET. Pp. 312. 297 Illustrations. (164 in colour). 12/6 net.

SURFACE ANATOMY
By A. ROBINSON, M.D., F.R.C.S., and E. B. JAMIESON, M.D. Pp. 182. 38 Illustrations. (24 in colour). 15/- net.

APPLIED PHYSIOLOGY
By SAMSON WRIGHT, M.D., M.R.C.P., with introduction by SWALE VINCENT, M.D., LL.D., D.Sc., F.R.S. (Ed. and Canada). New Edition ready October.

A MANUAL OF PHYSIOLOGY
By H. WILLOUGHBY LYLE, M.D., F.R.C.S., and DAVID DE SOUZA, M.D., D.Sc.(Lond.), F.R.C.P.(Lond.). 2nd. Edition. Pp. 840. 139 Illustrations. 21/- net.

AN INTRODUCTION TO PHARMACOLOGY & THERAPEUTICS
By J. A. GUNN, M.D., D.Sc.(Edin.), M.A.(Oxon.). Pp. 220. 5/- net.

A TEXTBOOK OF PHARMACEUTICAL CHEMISTRY
By A. O. BENTLEY, Ph.C., and J. DRIVER, Ph.D., M.Sc., A.I.C. Pp. 470. 6 Illustrations. 18/- net.

A TEXTBOOK OF THE PRACTICE OF MEDICINE
Edited by FREDERICK W. PRICE, M.D., F.R.S.(Edin.). New Edition ready October.

A MANUAL OF MEDICINE 3rd Edition. Pp. 502.
By A. S. WOODWARK, C.M.G., C.B.E., M.D., F Illustrated. 15/- net.

A MANUAL OF SURGERY
By A. THOMSON, M.D, F.R.C.S.(Edin.), and A. MILES, M.D., F.R.C.S.(Edin.).

Vol. I. General Surgery.	7th Edition.	Pp. 565.	169 Illustrations	12/6 net.
Vol. II. Extremities, Head and Neck.	7th Edition.	Pp. 682.	299 Illustrations.	12/6 net.
Vol. III. Thorax and Abdomen.	7t Edition.	Pp. 582.	169 Illustrations.	12/6 net.

(Continued on opposite page.)

OXFORD MEDICAL PUBLICATIONS

(Continued from opposite page.)

OPERATIVE SURGERY

By the same authors. 3rd Edition. Pp. 640. 279 Illustrations. 16/- net.

A MANUAL OF OPERATIVE SURGERY

By Sir HOLBURT J. WARING, C.B.E., M.B., M.S., B.Sc., F.R.C.S.
6th Edition. Pp. 886. 572 Illustrations. 18/- net.

A MANUAL OF SURGICAL ANATOMY: for Practitioners and Students

By LEWIS BEESLY, F.R.C.S.(Edin.), and T. B. JOHNSTON, M.B., Ch.B.
3rd Edition. Pp. 575. 166 Figs. 18/- net.

THE PRINCIPLES OF CLINICAL PATHOLOGY IN PRACTICE

By GEOFFREY BOURNE, M.D., M.R.C.P., and KENNETH STONE, M.D., M.R.C.P. Pp. 402. 10 Illustrations. 16/- net.

POST MORTEM APPEARANCES

2nd Edition.
By J. M. ROSS, M.B., M.R.C.S. Preface by E. H. KETTLE, M.D. Pp. 234. 7/6 net.

MANUAL OF BACTERIOLOGY

By ROBERT MUIR, M.A., M.D., Sc.D., F.R.S., and JAMES RITCHIE, M.A., M.D., F.R.C.P.(Edin.). 8th Edition. Pp. 848. 211 Illustrations. 6 Coloured Plates. 16/- net.

GYNÆCOLOGY WITH OBSTETRICS

By JOHN S. FAIRBAIRN, M.A., B.M., B.Ch.(Oxon.), F.R.C.P.(Lond.), F.R.C.S.(Eng.). 2nd Edition. Pp. 836. 167 Figs. 5 Plates. 25/- net.

TWEEDY'S PRACTICAL OBSTETRICS

Edited and largely rewritten by BETHEL SOLOMONS, M.D., F.R.C.P.I., M.R.I.A.
6th Edition. Pp. 781. 294 Illustrations. 25/- net.

KER'S MANUAL OF FEVERS

3rd. Edition. Revised by CLAUDE RUNDLE, O.B.E., M.D.(Lond.), M.R.C.S.(Eng.), L.R.C.P.(Lond.), D.P.H. Pp. 352. 6 Plates. 12/6 net.

KER'S INFECTIOUS DISEASES

3rd Edition. Revised by the same. Pp. 626. 32 Plates (14 in colour). 67 Charts. 9 Tables. 30/- net.

ELEMENTS OF HYGIENE AND PUBLIC HEALTH

2nd Edition.
By CHARLES PORTER, M.D., M.B., C.M., M.R.C.P.(Ed.). Pp. 440. 98 Illustrations. 14/- net.

PRACTICAL ANÆSTHETICS

By H. EDMUND BOYLE, O.B.E., M.R.C.S., L.R.C.P., and C. LANGTON HEWER, M.B., B.S., M.R.C.S. 3rd Edition. Pp. 200. 6/6 net.

HEWITT'S ANÆSTHETICS and their ADMINISTRATION

Re-edited throughout by HENRY ROBINSON, M.A., M.D., B.Ch.
5th Edition. Pp. 500. Illustrated. 30/- net.

X-RAYS AND RADIUM, An Introduction to the Study of

By HECTOR A. COLWELL, M.B., D.P.H.(Oxon.), and CECIL P. G. WAKELEY, F.R.C.S., F.R.S.(Edin.). Pp. 222. 37 Illustrations. 10/6 net.

HUNTER TOD'S DISEASES OF THE EAR

Revised and largely rewritten by GEORGE C. CATHCART, M.A., M.D.
2nd Edition. Pp. 347. 4 Coloured Plates. 87 Illustrations. 10/6 net.

MEDICAL ELECTRICITY FOR STUDENTS

By A. R. I. BROWNE. 2nd Edition. Pp. 265. 88 Illustrations. 12/6 net

A MANUAL OF VENEREAL DISEASES FOR STUDENTS

By BREVET-COL. L. W. HARRISON, D.S.O., M.B., Ch.B., M.R.C.P.E.
Pp. 360. 16 Coloured, and 6 Black and White Plates. 64 Figs. 16/- net.

A TEXTBOOK OF PSYCHIATRY for Students and Practitioners

By D. K. HENDERSON, M.D.(Ed.), F.R.F.P.S.(Glas.), and R. D. GILLESPIE, M.D.(Glas.), D.P.M.(Lond.). Pp. 532. 18/- net.

IMPORTANT NEW TEXTBOOK.

Demy 8vo. 992 pp. Illustrated. With an Index of over 5,000 references. 22s. 6d. net, Inland postage 9d.

A TEXTBOOK OF MEDICINE.

Edited by J. J. CONYBEARE, M.D.Oxon., F.R.C.P., Assistant Physician to Guy's Hospital.

CONTRIBUTORS—J. J. CONYBEARE, *M.C.*, M.D., F.R.C.P.; W. H. CRAIB, *M.C.*, M.B., M.R.C.P.; GEOFFREY B. DOWLING, M.D., M.R.C.P.; E. H. R. HARRIES, M.D., D.P.H.; ARTHUR MAITLAND-JONES, *O.B.E.*, *M.C.*, M.D., M.R.C.P.; VERNON E. LLOYD, *M.C.*, M.B., B.S.; HUGH MACLEAN, D.Sc., M.D., F.R.C.P.; GEOFFREY MARSHALL, M.D., F.R.C.P.; TREVOR OWEN, M.B., M.R.C.P.; F. M. R. WALSHE, D.Sc., M.D., F.R.C.P.

Crown 8vo. 700 pp. Illustrated with 73 X-Ray Half-tones. 15s. net, Inland postage 9d.

A HANDBOOK OF SURGICAL DIAGNOSIS.

By CLEMENT E. SHATTOCK, M.D., M.S.Lond., F.R.C.S., Surgeon to the Royal Free Hospital, Paddington Green Children's Hospital, and to the Mount Vernon Hosp. for Diseases of the Chest; Assist. Surg. to the Cancer Hosp.; Erasmus Wilson Demonstrator, Roy. Coll. of Surg., Lond.

Crown 8vo. 128 pp. Illustrated. 5s. net, Inland postage 4d.

ANTE-NATAL CARE.

A Practical Handbook of Ante-Natal Care and of the Abnormalities associated with Pregnancy.

By W. F. T. HAULTAIN, *O.B.E.*, *M.C.*, B.A., M.B.Camb., F.R.C.S.E., Senior Assistant Obstetric Physician to Ante-Natal Department, Edinburgh Royal Maternity and Simpson Memorial Hospital; and E. CHALMERS FAHMY, M.B.Edin., F.R.C.S.E., Assistant Obstetric Physician and Special Assistant to the same Department. With a Foreword by Professor R. W. JOHNSTONE, *C.B.E.*, M.A., M.D., F.R.C.S.E., Professor of Midwifery and Diseases of Women, University of Edinburgh.

Crown 8vo. 144 pp. 5s. net, Inland postage 4d.

HOW TO STAIN THE NERVOUS SYSTEM.

By J. ANDERSON, Head Laboratory Assistant, National Hospital for Diseases of the Nervous System, Queen Square, London. With an Introduction by J. G. GREENFIELD, B.Sc., M.D., F.R.C.P., Pathologist to the National Hospital.

Third Edition. Crown 8vo. 360 pp. 63 Illustrations. 8s. 6d. net, postage 6d.

Elements of Surgical Diagnosis.

By Sir ALFRED PEARCE GOULD. *Seventh Edition.* Revised by ERIC PEARCE GOULD, M.D., M.Ch.Oxon., F.R.C.S.Eng. Illustrated. 12s. 6d. net.

Materia Medica and Therapeutics.

By J. MITCHELL BRUCE, C.V.O., M.A., LL.D.Aberd., M.D., F.R.C.P.Lond., and Prof. WALTER J. DILLING, M.B., Ch.B.Aberd. *Thirteenth Edition.* Illustrated. 10s. 6d. net.

Diseases of the Nervous System.

By H. CAMPBELL THOMSON, M.D., F.R.C.P. Lond., and GEORGE RIDDOCH, M.D.Aberd., F.R.C.P.Lond. *Fourth Edition.* Illustrated. 16s. net.

A Manual of Chemistry for Medical Students.

By ARTHUR P. LUFF, C.B.E., M.D., B.Sc., F.R.C.P.Lond., and HUGH C. H. CANDY, B.A., B.Sc.Lond., F.I.C. *Seventh Edition,* in two volumes. Vol. I, Introduction and Inorganic Chemistry, 11s. net. Vol. II, Organic Chemistry, 6s. net.

X-Ray Diagnosis.

By J. MAGNUS REDDING, F.R.C.S.Eng. 244 pages, with 80 Radiographic Plates. 21s. net.

Clinical Methods.

By ROBERT HUTCHISON, M.D.Edin., F.R.C.P.Lond., and HARRY RAINY, M.D., F.R.C.P.Edin., F.R.S.E. *Eighth Edition.* Revised by ROBERT HUTCHISON. Illustrated. 12s. 6d. net.

Surgical Applied Anatomy.

By Sir FREDERICK TREVES, Bart. *Eighth Edition.* Revised by Prof. CHOYCE, C.M.G., C.B.E., B.Sc., M.D., F.R.C.S.Eng. Illustrated. 14s. net.

Diseases of the Nose and Throat.

By Sir STCLAIR THOMSON, M.D., F.R.C.P. Lond., F.R.C.S.Eng. *Third Edition.* Illustrated. 45s. net.

The Student's Handbook of Surgical Operations.

By Sir FREDERICK TREVES, Bart., and JONATHAN HUTCHINSON, F.R.C.S.Eng. *Fourth Edition.* Illustrated. 10s. 6d. net.

The Student's Handbook of Gynæcology.

By G. ERNEST HERMAN, M.B., F.R.C.P. Lond., F.R.C.S.Eng. *Second Edition.* With additions by R. DRUMMOND MAXWELL, M.D.Lond., F.R.C.S.Eng. Illus. 10s. net.

A Handbook of Midwifery:

For Midwives, Maternity Nurses, and Obstetric Dressers.

By COMYNS BERKELEY, M.A., M.C., M.D. Cantab., F.R.C.P.Lond., F.R.C.S.Eng. *Seventh Edition.* Illustrated. 8s. net.

A Manual of Physics for Medical Students.

By HUGH C. H. CANDY, B.A., B.Sc.Lond., F.I.C. (A Companion Volume to Luff and Candy's "Manual of Chemistry.") *Third Edition.* Revised and Enlarged. Illustrated. 7s. 6d. net.

CASSELL & CO., LTD., LA BELLE SAUVAGE, LONDON, E.C.4.

BAILLIÈRE, TINDALL & COX'S

BOOKS FOR STUDENTS

"The best text-book of Surgery in English."—*Lancet.*

TWELFTH EDITION

Rose & Carless' Surgery

Price 30s.

¶ "As a standard work on its subject it should be in the hands of every student, who will find everything set out in a full and interesting manner, devoid of surplus packing, and with the essential facts well emphasized."—*Durham University Gazette*

Demy 8vo. Pp. xii + 1,554, with 19 Coloured Plates an X-Ray Supplement containing 78 Photographs and 639 other Illustrations, and an appendix on Military Surgery.

THOROUGHLY REVISED, WITH THE ADDITION OF TWO NEW CHAPTERS.

SECOND EDITION

Bigger's Bacteriology

Price 12s. 6d.

¶ ". . . . In this book the author has succeeded admirably in expounding the principles of bacteriology free from the confusion of its many special refinements."—*Guy's Hospital Gazette.*

¶ ". . . It can be confidently recommended to those wishing to obtain a well-written, sound book of bacteriology of a reasonable length."—*St. Bartholomew's Hospital Journal.*

Size 8 in. × 5½ in. Pp. xvi + 452, with 5 Coloured Plates and 82 other Illustrations.

REVISED AND ENLARGED, WITH NEW ILLUSTRATIONS AND COLOURED PLATES.

FOURTEENTH EDITION

Green's Pathology

Price 21s. net.

¶ "Green's Pathology is and has been for many years a favourite with students, and this new edition will serve to add to its value. The illustrations are profuse and good, and the students can want no better guide to an understanding of what is always a difficult and confusing subject."—*Middlesex Hospital Journal.*

Demy 8vo. Pp. viii + 650, with 261 Illustrations and 9 Coloured Plates.

"It contains more than enough to get a man through any examination."—*St. Bartholomew's Hospital Journal.*

FIFTH EDITION

Buchanan's Anatomy

Price 35s.

REVISED AND EDITED BY THE COMMITTEE OF TEACHERS IN ANATOMY.

¶ "We can cordially and confidently recommend it, not only as a reliable and helpful guide through the dangers of the examination room but also as a practical book of reference throughout the years of professional life."—*British Medical Journal.*

Demy 8vo. Pp. xvi + 1,702 with 810 Illustrations, plain and in colour.

"This book contains a good deal of useful information and much sound advice."—*Lancet.*

FIFTH EDITION

Lamb's Throat, Nose & Ear

Price 12s. 6d.

Revised by F. W. SYDENHAM, M.D., C.M., F.R.C.S.Edin., Honorary Surgeon, Birmingham Ear and Throat Hospital.

¶ "It should be read by all students doing ear, throat, and nose dresserships. The chapters on treatment are excellent."—*Middlesex Hospital Journal.*

Pp. xvi + 450, with 73 Illustrations, with X-Ray Supplement of 31 Plates.

"A book which is a credit to British Dermatology."—*British Journal of Dermatology.*

SECOND EDITION

Mackenna's Skin

Price 25s.

¶ "The second edition of this text-book ranks it as one of the best on skin diseases to be obtained at the present day. For students it is an essentially sound book, and very readable: for practitioners, helpful in diagnosis, and both reliable and clear in lines of treatment."—*St. Bartholomew's Hospital Journal*

Royal 8vo. Pp. xii + 450, with 36 Coloured Plates, 143 Illus., and many Formulæ.

7 & 8, Henrietta Street, Covent Garden, London, W.C.2.

By G. PERCIVAL MILLS, M.B., B.Sc.Lond., F.R.C.S.; and H. HUMPHREYS, M.B., Ch.B., B.D.S.Birm., L.D.S.Eng. Third Edition. xii + 344 pages, 57 illustrations. 14s. net.

London: EDWARD ARNOLD & CO., 41-43, Maddox St., W.1.

MODERN MEDICAL MONOGRAPHS

Designed specially for the practitioner

Edited by **HUGH MACLEAN**, M.D., D.Sc., F.R.C.P., Prof. of Medicine, Univ. of London.

A NEW VOLUME.

HEART DISEASE IN CHILDHOOD

by

H. B. RUSSELL, M.D., M.R.C.P., and
C. K. J. HAMILTON, B.M., M.R.C.P.

Demy 8vo. 104 pages. 7s. 6d. net.

Heart disease presents special problems in the child, not only because of the difficulties in the diagnosis and management of cases of congenital heart disease but also—and a much more important reason—because it is in childhood that the acute infective phase of rheumatic heart disease most often occurs, and on the treatment of that phase may depend the outlook of the patient's whole life.

"The authors have treated their subject in a lucid and most able manner, discussing the problems with which every practitioner has to contend, and explaining methods of diagnosis and treatment."—MEDICAL TIMES.

"This book will be warmly welcomed dealing as it does with a subject which is engaging so much attention at the present time."—NURSING TIMES.

A NEW EDITION.

MODERN METHODS OF FEEDING IN INFANCY AND CHILDHOOD

by

D. PATERSON, B.A., M.D., F.R.C.P., and
J. FOREST SMITH, M.R.C.P.

Demy 8vo. 162 pp. Second Edition. 7s. 6d. net.

"The first edition of . . . appeared in 1926, and has well established itself as one of the most useful and practical of the shorter books on this subject. The second edition is larger by some 40 pages, and contains additions which considerably increase its utility and completeness. . . . These chapters are admirably clear and practical, giving definite indications of quantities required and stressing common dietetic errors such as excess of carbohydrate and of milk."—LANCET.

"It constitutes a very complete guide in all the difficult details of dieting a delicate infant."—NURSING MIRROR.

"It will certainly prove to be a popular book because it is concise and dogmatic, and expresses opinions in an easily remembered fashion."—BRITISH MEDICAL JOURNAL.

MODERN VIEWS ON DIGESTION AND GASTRIC DISEASE

HUGH MACLEAN, M.D., D.Sc., F.R.C.P. (Prof. of Medicine, London University). Second Ed. 12s. net.

The present-day position of gastric physiology and pathology is here presented in a most lucid and able manner. Professor Maclean emphasises the fact that intelligent treatment of gastric diseases must be based on physiological knowledge. In this monograph he also gives full details for medical treatment of duodenal ulcers, and proves that recourse to surgical measures is not generally necessary in order to bring about successful results.

"It is not surprising that Prof. Hugh Maclean's volume entitled *Modern Views on Digestion and Gastric Disease* has rapidly passed into a second edition."—BRITISH MEDICAL JOURNAL.

"It presents an excellent résumé of present day knowledge and the author's experience enables him to give much practical advice on diagnosis and treatment."—PRESCRIBER.

"The general reading of the book by practitioners of general medicine will greatly improve the standards of practice in the difficult subject of gastric disease."—CANADIAN JOURNAL OF MEDICINE AND SURGERY.

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF GLYCOSURIA AND DIABETES

HUGH MACLEAN, M.D., D.Sc., F.R.C.P. (Prof. of Medicine, London University). Fourth Ed. 12s. net.

"Of the successful series edited by Prof. Hugh Maclean of *Modern Medical Monographs*, the first by himself on Glycosuria and Diabetes was brought out in 1922, and is now in its fourth edition, a testimony to its popularity which almost absolves the reviewer from further comment."—BRITISH MEDICAL JOURNAL.

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF RENAL DISEASE

HUGH MACLEAN, M.D., D.Sc., F.R.C.P. (Prof. of Medicine, London University). Third Ed. 12s. net.

"This extremely useful handbook is both scientific and thoroughly practical, and thus has rightly been recognized as a book to buy and keep at hand for reference and advice in emergencies."—BRITISH MEDICAL JOURNAL.

THE ENDOCRINES IN GENERAL MEDICINE

by

W. LANGDON BROWN, M.A., M.D., F.R.C.P.

Demy 8vo. 152 pages. 7s. 6d. net.

"This little book is written primarily for the general practitioner, who will find in it an account of the endocrine system and its diseases presented in a form which should certainly be of service to them."—LANCET.

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS

by

R. C. WINGFIELD, B.A., M.B.(Oxon.), F.R.C.P.

Demy 8vo. 144 pages. 10s. 6d. net.

"It is definitely addressed to the general practitioner, and in short, compact, dogmatic chapters it presents just the information and guidance which the average medical adviser will appreciate."—BRITISH JOURNAL OF TUBERCULOSIS.

BACTERIA VACCINES AND THEIR POSITION IN THERAPEUTICS

by

LEONARD S. DUDGEON, C.M.G., C.B.E., F.R.C.P.

Demy 8vo. 96 pages. 7s. 6d. net.

"This book should prove most helpful to all those who are interested in the subject."—BRITISH MEDICAL JOURNAL.

"We can confidently recommend this handy and up-to-date volume on vaccine therapy."—MEDICAL TIMES.

MODERN VIEWS ON THE TOXÆMIAS OF PREGNANCY

by

O. L. V. de WESSELOW, M.B., F.R.C.P., and
J. M. WYATT, M.B., F.R.C.P.

Demy 8vo. 108 pages. 7s. 6d. net.

"The authors have succeeded in collecting and presenting in a readable form the more important facts gained from recent scientific research, and this book will certainly afford some guidance in the management of difficult cases."—B.M.J.

MODERN DIAGNOSIS AND TREATMENT OF SYPHILIS CHANCROID AND GONORRHŒA

L. W. HARRISON, D.S.O., M.B., Ch.B., M.R.C.P.E.

Demy 8vo. 176 pages. 10s 6d. net.

This is a handy volume written by an admitted authority on venereal disease. It deals with the clinical diagnosis, prevention, and treatment of syphilis, including a useful chapter on the management of syphilis; the general principles of treatment of gonorrhœa are clearly presented and modern methods of treatment lucidly described."—BRITISH MEDICAL JOURNAL.

"It gives a lucid and concise account of syphilis, chancroid and *gonorrhœa* in all their manifestations, and with the sections on diagnosis and treatment no fault can be found. To the busy practitioner who cannot overtake the modern literature it should be very useful."—LANCET.

SURGICAL PATHOLOGY

By CECIL P. G. WAKELEY, F.R.C.S.(Eng.), F.R.S.(Edin.),
Hunterian Professor, Royal College of Surgeons of England; Surgeon, King's College Hospital;
and ST. J. D. BUXTON, M.B., B.S.(Lond.), F.R.C.S.(Eng.),
Surgeon and Orthopædic Surgeon, King's College Hospital.

WITH 392 ILLUSTRATIONS (50 FULLY COLOURED).

British Medical Journal:—"A good book on surgical pathology is a thing to be prized . . . as a practical, useful, and comprehensive guide to the subject, whether for students or practitioners, their book could not be bettered. Special care has obviously been taken with the index, which is commendably full and clear. The authors' manner of writing has a freshness and directness which certainly aids in maintaining interest . . . their illustrations are uniformly good and instructive. The whole plan and execution of the work is good, and as the authors' position is a guarantee that the information contained in it is authoritative, there is every reason to think that the book will be used and appreciated. Students have long felt the need of a work of this kind, and it exactly meets the need."

Super Roy. 8vo. 722 pp. Bevelled Boards. With 130 Illustrations, some in Colour. 42s. net. Postage 1s.

AN INDEX OF SYMPTOMATOLOGY

By Twenty-six Distinguished Contributors.

Edited by H. LETHEBY TIDY, M.A., M.D.Oxon., F.R.C.P.Lond.,
Assistant Physician, St. Thomas's Hospital; Consulting Physician, Royal Northern Hospital.

This book is intended to provide an account of the symptomatology of diseases. The general object has been to give a clear and reasonably full description of the clinical manifestations of each disease, without dwelling unduly on minor complications and variations.

British Medical Journal:—"Should help considerably in the solution of difficult diagnostic problems. The articles, which cover all branches of medicine, surgery, gynæcology, and the specialties, are tersely written and well up to date. The book is illustrated with four beautiful coloured plates and a number of reproductions of photographs and charts. The radiograms are clear and convincing. . . . Dr. Tidy and his collaborators are to be congratulated on producing a volume worthy of the series to which it belongs."

Bristol: JOHN WRIGHT & SONS Ltd. [Illustrated Catalogue free.] **London: SIMPKIN MARSHALL Ltd.**

LIPPINCOTT BOOKS.

FRACTURES AND DISLOCATIONS: Treatment and After-Care. 2ND EDITION REVISED.
By PHILIP D. WILSON, M.D., and WILLIAM A. COCHRANE, M.D. 45s.
"We can safely recommend this book as one of the best and most up-to-date guides for the general practitioner, as well as for the expert surgeon and the student."—*British Medical Journal.*

PEDIATRICS for the GENERAL PRACTITIONER.
By HARRY MONROE McCLANAHAN, A.M., M.D. 230 Illustrations. 25s.
"This is a volume which is admirably suited to the needs of the practitioner."—*British Medical Journal.*

TEXTBOOK OF UROLOGY for Students and Practitioners.
By DANIEL N. EISENDRATH, M.D., and HARRY C. ROLNICK, M.D. 700 black and white Illustrations and 11 in colour. 42s.
This textbook on Urology presents the subject in the simplest possible manner.
"The book is admirably produced, and contains seven hundred illustrations in black and white, and eleven in colour, many of them really beautiful. . . ."—*The Practitioner.*

SPALTEHOLZ HAND ATLAS OF HUMAN ANATOMY.
Edited and Translated from the Seventh German Edition. Fifth Edition in English. Three Volumes. Octavo. Cloth. With Coloured Illustrations throughout. 902 pages. 80s.

INTERNS HANDBOOK.
A Guide to Rational Drug Therapy, Clinical Procedures, and Diets.
By Members of the Faculty of the College of Medicine, Syracuse University. Under the direction of M. S. DOOLEY, A.B., M.D. 12s. 6d.
Directions are so given as to prevent indecision in emergencies. Information needed in using standard drugs is given in the Drug Section; it is not a mere list of titles.

NEUROSURGERY: Principles, Diagnosis, and Treatment.
By WILLIAM SHARPE, M.D., and NORMAN SHARPE, M.D. Profusely Illustrated. 42s.
This book covers the Surgery of the Brain, Spinal Cord, and the Central Nervous System.

OBSTETRICS: Normal and Operative.
By GEORGE PEASLEE SHEARS, B.S., M.D. Sixth Edition Revised. 423 Illustrations. 38s.

BRAIN AND SPINAL CORD.
By EMIL VILLIGER, M.D., of the University of Basel. Translated, with Additions, by GEORGE A. PIERSOL, M.D., Sc.D. Third Edition. 262 Illustrations, many in Colours. 25s.

The Only Surgical Work in the World that is always up to date

WE invite your attention to Nelson's "Loose-Leaf Living Surgery." It consists of 7 volumes and Index, surveying the entire scheme of modern surgery. It is bound in loose-leaf style so that pages may be added under any heading. Twice a year a résumé of the latest world knowledge on surgery is printed and sent to subscribers for insertion in their books. From hundreds of sources the subscriber is made acquainted with the latest international surgical knowledge and technique.

The editor-in-chief is ALLEN O. WHIPPLE, M.D., Professor of Surgery, Columbia University. Men of such calibre as our own A. J. WALTON, PUTTI of Bologna, GASTON LABAT of Montpelier University, and THORKILD ROVSING of Copenhagen contribute.

The volumes are divided as to the main subjects along the following lines:—Vol. 1: Pathology, Technic, Legal Relations, etc. Vol. 2: Head and Neck, Tuberculosis, Diabetes, Nervous System, etc. Vol. 3: Chiefly Orthopædic. Vol. 4: Heart, Breast, and Lungs, etc. Vol. 5: Abdominal. Vol. 6: Urology. Vol. 7: Gynecology. There are thousands of illustrations of a strikingly clear and informative character.

It will be a pleasure to send you any one or more of the books (even the complete set) to look over without asking you to assume the slightest obligation to purchase.

New and 18th Edition, thoroughly revised, of this Standard Work.

HANDBOOK OF PHYSIOLOGY

By Prof. W. D. HALLIBURTON, M.D., LL.D., F.R.C.P., F.R.S.,
Emeritus Professor of Physiology, King's College, London, and
Prof. R. J. S. McDOWALL, M.B., D.Sc., F.R.C.P.(Edin.),
Dean of the Faculty of Medicine and Professor of Physiology, King's College, London.

British Medical Journal.—"This textbook to-day meets us 'completely revised,' authoritative, venerable—but with no signs of senescence, none of that irritability which may come with age, no weariness of the flesh."

Physiological Abstracts.—"The book keeps up its reputation as a very readable and reliable exposition for students of physiology."

Science Progress.—"The outstanding features which characterise this textbook over and above its clear and complete exposition are balance and impartiality in the discussion of various explanations of physiological activities."

With over 500 Illustrations, many of which are coloured, and 3 coloured plates. 18s. net.

THE

MEDICAL INSURANCE AGENCY Ltd.

(LIMITED BY GUARANTEE).

The provision of Educational expenditure is a matter of considerable consequence to members of the profession who desire to afford their children the same facilities they themselves enjoyed.

The vital years in education are expensive, and, to provide the necessary funds, Children's Educational Policies have been designed.

Under these schemes a child's education is absolutely secured whether the parent lives or dies, and the burden of educational expenses is reduced by spreading the cost over a longer period.

The period of payments and benefits can be fixed to suit individual requirements.

Rates for any period and any particular age will be quoted on application.

If you are in any doubt, use The Medical Insurance Agency—its service and its unbiased advice—for ***the M.I.A. exists to save your money and protect your interests.***

The Agency helps in the education of necessitous cases by means of

1. The Educational Grants (Girls) Subcommittee, undertaking the education, in selected cases, of daughters of medical men and women deceased, or in necessitous circumstances.
2. The establishment of a Dawson Williams Presentation Scholarship at Epsom College for the son of a medical man and woman.
3. Grants to the General Funds of Epsom College, amounting to £4,158.
4. Grants to the Royal Medical Benevolent Fund Guild partly spent on the education of girls and young children.

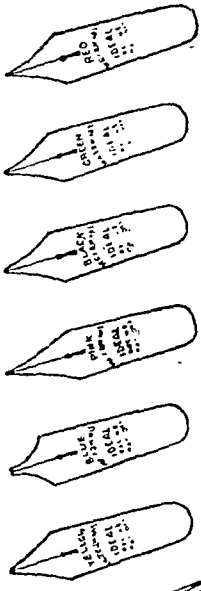
9 out of 10 busy medical men find their ideal nib in this No 7 series

RED
GREEN
BLACK
PINK
BLUE
YELLOW
GREY



Another Waterman innovation to save time and trouble in pen selection. Each of the seven pens comprising the No. 7 series has a different kind of nib—indicated by a colour inlay band in the cap. You can choose the nib to your liking in a minute from this selection, and for re-ordering you have only to quote the colour of the inlay band and an exact duplicate is at once available. The No. 7 Pen is a large size Waterman's, exquisitely made in the now famous ripple rubber. Its 9ct. gold band gives additional attraction to a very beautiful pen. Price 37/6.

The colour bands specify:—RED Standard Medium. GREEN Manifold. BLACK Flexible Medium. PINK Fine Flexible. BLUE Short Stub. YELLOW Turned Up. GREY Short Stub Oblique.

COLLENDER'S SPLINTS

(Patented in the Leading Countries of the World)

An evolution of the Thomas Splint—all the advantages of the Thomas Splint are preserved, with many important improvements, additions, and modifications.
They are supplied in strong fitted case, and enable 10 fractures simultaneously to be put up in any position obtainable by Thomas arm or leg Splints.
They provide the most modern methods of accurate extension, and safe transport of the patient is assured. Complete splints suited to limbs of any dimensions can be constructed in a few minutes from the component parts.

All members are interchangeable, standardised, numbered, and replaceable. They are made of Duralumin, which is untarnishable, exceedingly light in weight, and of great tensile strength. They can be immersed in sterilizing fluid without injury and can be used repeatedly.
Collender's Splints will be found invaluable for Hospital Emergency work and particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

PEAT in the TREATMENT of SKIN DISEASES

THE effectiveness of the peat distillate principle in the treatment of skin diseases is sufficiently well known to need no comment. Sphagnol preparations contain this principle in a convenient medium. The medical soap, the ointment, the lotion, the suppositories allow of your using the properties of peat in the manner most suitable to the case in question.

The manufacturers make no more extravagant claim than this. They simply state that Sphagnol preparations provide the peat distillate principle in a convenient medium, and that they can be purchased for a reasonable price at any chemist's shop. They are prepared to submit samples for you to judge their claims. If you are a medical practitioner simply write to Peat Products (Sphagnol) Ltd., Dept. B15, 21, Bush Lane, London, E.C.4.

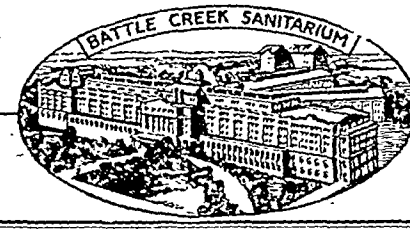
R ANDERSON & SON
1 HILL PLACE EDINBURGH

A special food for changing the intestinal flora

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State, COATES & COOPER, 41, Great Tower Street, London, E.C.3.

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs.

Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.



LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO., Mich., U.S.A.

This preparation is now obtainable in 5-oz. bottles.

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz.:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally.

In all the various forms of loss of nerve power Mist. Damianæ Co. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required. Dose: One or Two Drachms in Water.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles. Price in England 12/6 per pound.

Introduced and Prepared only by— C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte St., LONDON, E.C.2.

INTESTINAL SUBINFECTION

SALVITAE is the key whereby the physician may control elimination and alkalinization, thus dealing fundamentally and effectively with Intestinal Subinfection, Toxæmia, Acidosis, Uric-acidæmia, and Constipation.

It is indicated in a large number of disorders characterized by, and more or less dependent upon, faulty metabolism, imperfect elimination, and disturbances of the acid-base equilibrium of the body.

Samples and Literature on request to Sole Agents: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

A formula that demonstrates its scientific value.

Salvitae

Manufactured by American Apothecaries Co., New York.

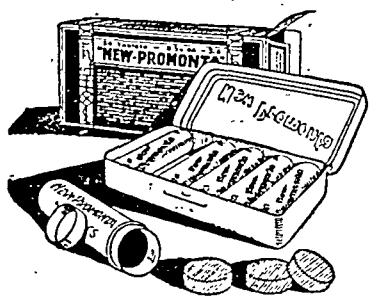
A RECOGNISED FOOD FOR CASES OF NERVOUS DISORDERS

"NEW-PROMONTA" occupies a unique position among remedial treatments for disorders of the nerves. "NEW-PROMONTA" possesses a definite organ specificity which makes its action exceedingly speedy and very reliable. In preparing "NEW-PROMONTA" great care is taken to preserve unchanged as to quantity and quality the Lipoids, Phosphatides, and Cholesterols found in the living nerve cells. As a result of its specific action "NEW-PROMONTA" begins at once to assist healthy metabolism in the nerve and brain cells, stimulating, nourishing, and restoring them.

Apart from these specialized functions the presence in "NEW-PROMONTA" of other nutritives such as Lime, Iron, Haemoglobin, and the Vitamins A, B, D, and E, render it particularly suitable as a tonic food during convalescence, for restoring physical well-being, and for counteracting the weakening effects of illness.

TO TEST "NEW-PROMONTA."

A trial supply of "NEW-PROMONTA," together with a collection of authoritative data on its composition and the tests to which it has already been subjected, will be sent post free to any Doctor, Clinic, or Hospital on application.



"NEW-PROMONTA" in Tabet form is supplied in handy boxes containing 54 tablets at 3/6. Each box includes a metal container for the pocket, which holds a day's supply. "NEW-PROMONTA" in Powder form is supplied in sealed air tight boxes of ½ lb. at 3/- and ¼ lb. at 5/6.

NEW-PROMONTA

FOR INTERNAL TREATMENT OF

GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal-Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2.

A-K

SANTAL MIDY

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

JB95

WHY HOVIS MATTERS

Largest VITAMIN B Content

Important Conclusions

The question as to what form of bread provides the essential Vitamin B most completely and economically has now been settled by independent experiments.

It is shown that in 100 g. dried bread the content of Vitamin B in milling products and yeast is:

White Bread	200
Wholemeal Bread	1,450
HOVIS Germ Bread	2,600

That the presence of the Vitamin is essential actively to promote health in adults and sturdy growth in children, is generally accepted from continued observation.
Wheat is rich in Vitamin B and the germ is the richest part.

HOVIS is made from the white flour, with the germ added. This gives HOVIS its pre-eminent position as a basic ration.

You obtain—as demonstrated by series of experiments by independent investigators—a greater active nutritive value from HOVIS than from any other cereal.

You need a smaller amount of HOVIS than any other bread for the proportion of nourishment received. This is a matter of very practical importance, especially where, as in so many homes and institutions, bread of necessity forms a large part of the daily diet. With children especially, a far larger amount of Vitamin B is supplied to them when fed on HOVIS.

One slice of HOVIS weighing 1 oz. contains as much Vitamin as 2 oz. of Wholemeal, and as 5 to 6 g. of fresh yeast.

Everybody likes it—another practical consideration, especially with children, and it is digested nearly as easily as white bread, and much more so than wholemeal.

Bowel Infection

in

DISEASES OF THE NERVOUS SYSTEM

A generation ago the origin of diseases of the nervous system presented for the most part a tangle of insoluble medical problems. The scientific worker of to-day, however, has so far cleared a way through the jungle as to make its ultimate conquest a certainty. In disorders of the nervous, as of other bodily systems, the overwhelming part played by toxæmic agencies has become generally recognised.

> "The first routine duty of the physician called upon to face nervous symptoms in which there is no known cause, such as arsenic, lead, or alcohol, is to search for a focus of infection. In some cases this will be found in the nasal cavity and its accessory sinuses, or in the mouth or pharynx, but in the great majority the seat of mischief lurks in the bowel. Should constipation and anæmia be associated with otherwise obscure nervous symptoms, there need be little hesitation concerning the diagnosis, and still less about the treatment. Bowel toxæmia proclaims itself in the boldest of type and the experienced physician often recognises auto-intoxication at a glance. Happily, in all such cases, now that the problem of intestinal disinfection has been solved by the introduction of the benzene derivative Dimol, it is possible to clear out the immediate cause of the trouble *in situ*."
>
> ———, M.D.(Ed.), Cavendish Square, W.1.

A new era in the treatment of many diseases of the nervous system is thus opened up by the discovery of this benzene derivative. With the introduction of Dimol, the *bactericidal equivalent* of 140 grains pure phenol can be administered four or five times a day without affecting the mucosa or producing any toxic effect whatever.

Samples and Literature will be sent on application to the

Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

WRIGHT'S LYSOL

You use Wright's Lysol in your own Surgery; your patients should surely have the same certain protection available in their homes. Emphasise the name 'Wright's' when prescribing Lysol. It is perfectly pure, non-irritant, and does not sting or roughen the most delicate skin. Made under the strict Rideal-Walker control test, its high quality can never vary: in proper dilution it gives positive results.

Wright's Lysol is the product of a firm that has specialized in disinfectants for over sixty years. Its reputation is just as unimpeachable as that of the famous Wright's Coal Tar Soap — and for the same reason — *constant purity.*

INSULIN "A.B."

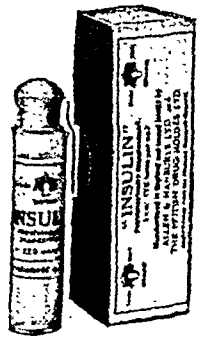
TRADE A B MARK Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Packed in bottles containing:

5 c.c. (100 units or 10 doses) 2/- each

Intestinal Disinfection

BACILLUS COLI BACILLURIA AND URINARY INFECTIONS

CONDITIONS dependent upon infection of the urinary tract by *B. coli* are by no means uncommon, and present varying degrees of severity, from serious suppurative lesions of the kidney to mild bacilluria of little importance.

The mechanism of infection by *B. coli* in these cases is uncertain, but it may depend upon minute lesions of the mucous membrane of the bowel through which it passes, together with probably an increase in the numbers of a particular and more virulent type (hæmolytic varieties of *B. coli* are common in urinary infections in the male).

If, then, disinfection of the intestinal canal is accomplished, these forms are destroyed, and those already located in the urinary tract may be attacked by a urinary antiseptic. By the combined administration of Kerol, urotropin (hexamine) and acid sodium phosphate, the treatment of urinary infections by *B. coli* is placed on a rational basis, and many cases are cured by this line of treatment when they fail to yield to urotropin alone.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

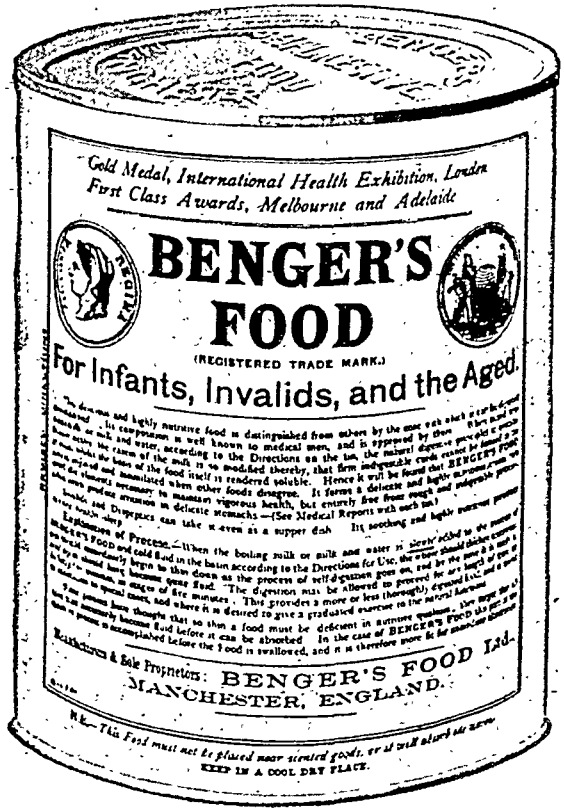
Most useful and efficient for the relief of Bronchial Asthma, Whooping Cough, Hay-Fever, Hypotonia, etc. Characterised by its negligible by-effects, prolonged action, and reliable therapeutic effect.

In 20 cases of Whooping Cough, relief from spasm and vomiting occurred in 18 of the patients.

Price: 4/6 per 8-oz. bottle; 16-oz., 8/-.

FULL LISTS ON APPLICATION.



Benger's Food—*the adjustable diet.*

The "LANCET" describes it as "Mr. Benger's admirable preparation."

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient.*

Benger's Food is prepared with fresh cows' milk. It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing. The process may be arrested at any time by simply bringing the mixture to the boil. (A useful average time for standing is 15 minutes).

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd.

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—
